Complex Pipelining

Daniel Sanchez
Computer Science and Artificial Intelligence Laboratory
M.I.T.

Complex Pipelining: Motivation

Instruction pipelining becomes complex when we want high performance in the presence of

- Multi-cycle operations, for example:
 - Full or partially pipelined floating-point units, or
 - Long-latency operations, e.g., divides
- Variable-latency operations, for example:
 - Memory systems with variable access time
- Replicated function units, for example:
 - Multiple floating-point or memory units

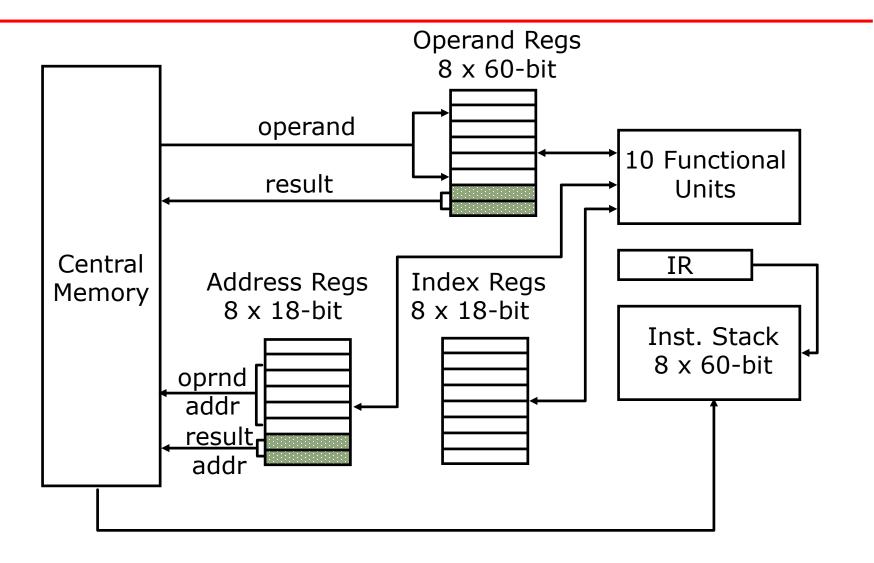

CDC 6600 Seymour Cray, 1963

- A fast pipelined machine with 60-bit words
 - 128 Kword main memory capacity, 32 banks
- Ten functional units (parallel, unpipelined)
 - Floating Point: adder, 2 multipliers, divider
 - Integer: adder, 2 incrementers, ...
- Hardwired control
- Dynamic scheduling of instructions using a scoreboard
- Ten Peripheral Processors for Input/Output
 - A fast multi-threaded 12-bit integer ALU
- Very fast clock, 10 MHz (FP add in 4 clocks)
- >400,000 transistors, 750 sq. ft., 5 tons,
 150 kW, new freon-based cooling technology
- Fastest machine in world for 5 years (until CDC 7600)
 - Over 100 sold (\$7-10M each)

CDC 6600: Datapath

CDC 6600: A Load/Store Architecture

- Separate instructions to manipulate three types of reg.
 - 8 60-bit data registers (X)
 - 8 18-bit address registers (A)
 - 8 18-bit index registers (B)
- All arithmetic and logic instructions are reg-to-reg

$$Ri \leftarrow (Rj) \text{ op } (Rk)$$

Only Load and Store instructions refer to memory!

6	3	3	18	
opcode	i	j	disp	$Ri \leftarrow M[(Rj) + disp]$

Touching address registers 1 to 5 initiates a load

6 to 7 initiates a store

- very useful for vector operations

CDC6600: Vector Addition

Ai = address register

Bi = index register

Xi = data register

more on vector processing later...

We will present complex pipelining issues more abstractly ...

Floating Point ISA

Interaction between the Floating point datapath and the Integer datapath is determined largely by the ISA

MIPS ISA

- separate register files for FP and Integer instructions the only interaction is via a set of move instructions (some ISAs don't even permit this)
- separate load/store for FPR's and GPR's but both use GPR's for address calculation
- separate conditions for branches
 FP branches are defined in terms of condition codes

Floating Point Unit

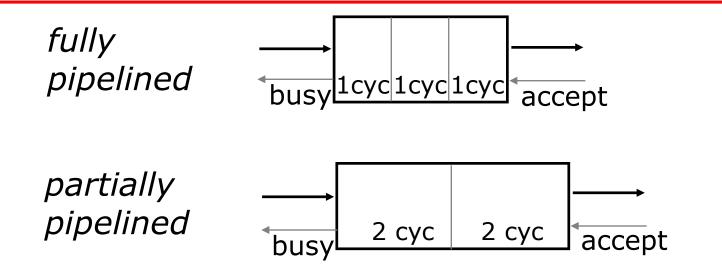

Much more hardware than an integer unit

Single-cycle floating point unit is a bad idea - why?

- it is common to have several floating point units
- it is common to have different types of FPUs Fadd, Fmul, Fdiv, ...
- an FPU may be pipelined, partially pipelined or not pipelined

To operate several FPUs concurrently the register file needs to have more read and write ports

Functional Unit Characteristics

Functional units have internal pipeline registers

- ⇒ operands are latched when an instruction enters a functional unit
- ⇒ inputs to a functional unit (e.g., register file) can change during a long latency operation

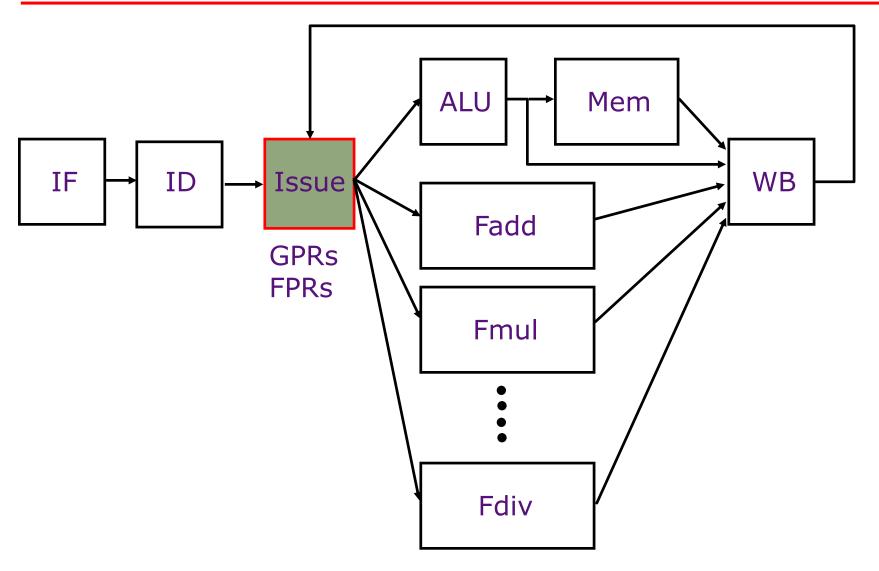

Realistic Memory Systems

Latency of access to the main memory is usually much higher than one cycle and often unpredictable Solving this problem is a central issue in computer architecture

Common approaches to improving memory performance

- separate instruction and data memory ports
 ⇒ no self-modifying code
- caches single cycle except in case of a miss ⇒ stall
- interleaved memory multiple memory accesses ⇒ bank conflicts
- split-phase memory operations
 out-of-order responses

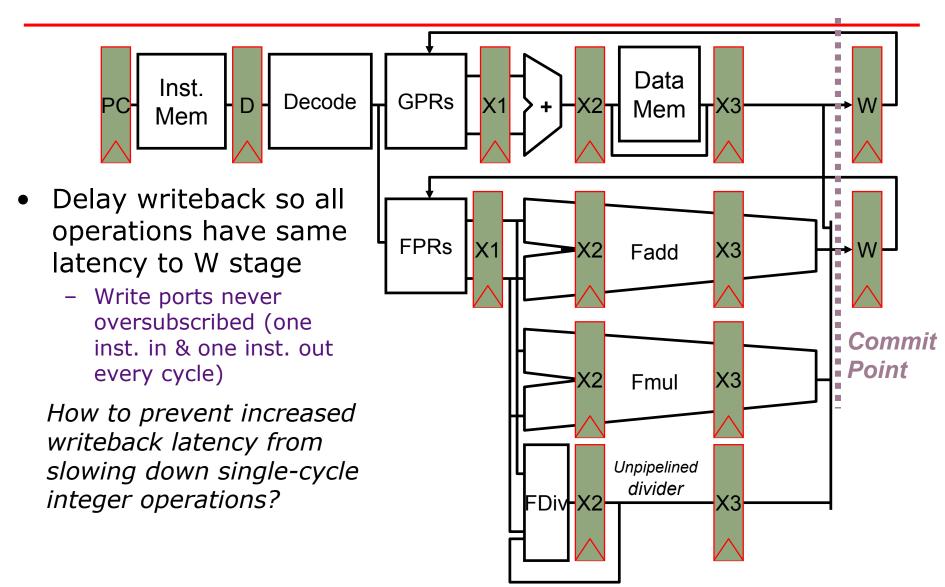

Complex Pipeline Structure

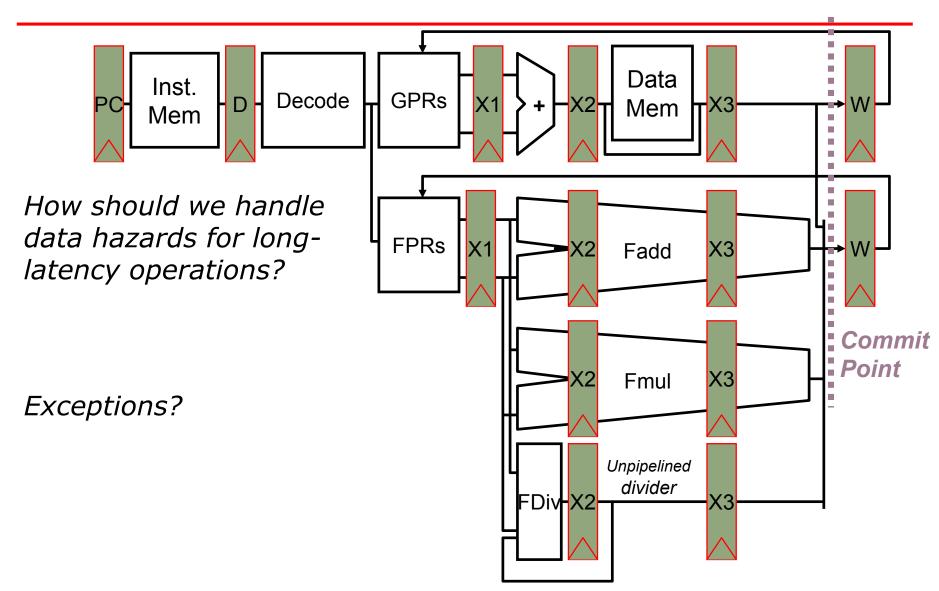

Complex Pipeline Control Issues

- Structural hazards at the execution stage if some FPU or memory unit is not pipelined and takes more than one cycle
- Structural hazards at the write-back stage due to variable latencies of different function units
- Out-of-order write hazards due to variable latencies of different function units
- How to handle exceptions?

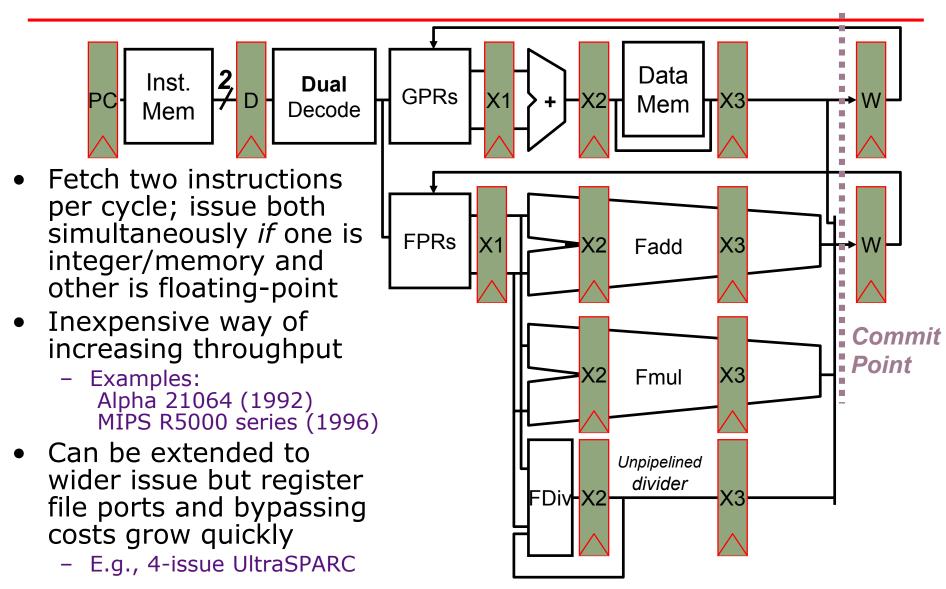

Complex In-Order Pipeline

Complex In-Order Pipeline

Superscalar In-Order Pipeline

Dependence Analysis

Needed to Exploit Instruction-level Parallelism

Types of Data Hazards

Consider executing a sequence of

$$r_k \leftarrow (r_i) \text{ op } (r_i)$$

type of instructions

Data-dependence

$$r_3 \leftarrow (r_1) \text{ op } (r_2)$$

 $r_5 \leftarrow (r_3) \text{ op } (r_4)$

Read-after-Write (RAW) hazard

Anti-dependence

$$r_3 \leftarrow (r_1)$$
 op (r_2) Write-after-Read $r_1 \leftarrow (r_4)$ op (r_5) (WAR) hazard

(WAR) hazard

Output-dependence

$$(r_3 \leftarrow (r_1) \text{ op } (r_2))$$

 $(r_3 \leftarrow (r_6) \text{ op } (r_7))$

Write-after-Write (WAW) hazard

L06-18

Detecting Data Hazards

Range and Domain of instruction i

- R(i) = Registers (or other storage) modified by instruction i
- D(i) = Registers (or other storage) read by instruction i

Suppose instruction j follows instruction i in the program order. Executing instruction j before the effect of instruction i has taken place can cause a

RAW hazard if $R(i) \cap D(j) \neq \emptyset$ WAR hazard if $D(i) \cap R(j) \neq \emptyset$ WAW hazard if $R(i) \cap R(j) \neq \emptyset$

Register vs. Memory Data Dependences

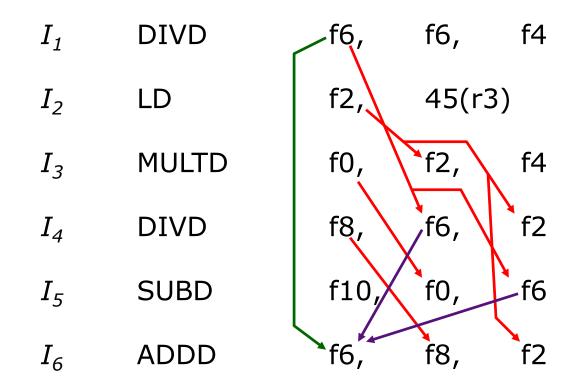

- Data hazards due to register operands can be determined at the decode stage but
- Data hazards due to memory operands can be determined only after computing the effective address

```
store M[(r1) + disp1] \leftarrow (r2)

load r3 \leftarrow M[(r4) + disp2]

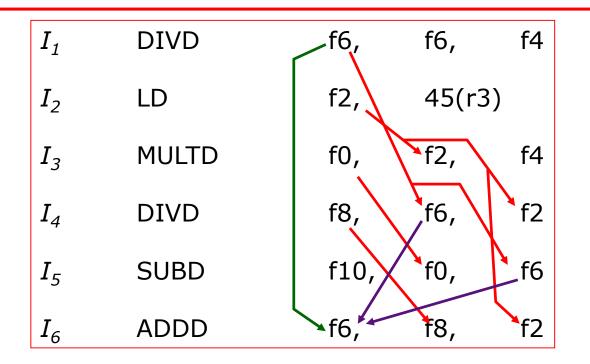

Does (r1) + disp1 == (r4) + disp2?
```

Data Hazards: An Example

RAW Hazards WAR Hazards WAW Hazards

What problems can out-of-order comp cause?

Scoreboard: A Hardware Data Structure to Detect Hazards Dynamically

Complex Pipeline

When is it Safe to Issue an Instruction?

- Approach: Stall issue until sure that issuing will cause no dependence problems...
- Suppose a data structure keeps track of all the instructions in all the functional units
- The following checks need to be made before the Issue stage can dispatch an instruction
 - Is the required function unit available?
 - Is the input data available? \Rightarrow RAW?
 - Is it safe to write the destination? ⇒ WAR? WAW?
 - Is there a structural conflict at the WB stage?

A Data Structure for Correct Issues

Keeps track of the status of Functional Units

Name	Busy	Ор	Dest	Src1	Src2
Int					_
Mem					
Add1					_
Add2					
Add3					
Mult1					
Mult2					
Div					

The instruction i at the Issue stage consults this table

FU available?

RAW?

WAR?

WAW?

An entry is added to the table if no hazard is detected; An entry is removed from the table after Write-Back

Simplifying the Data Structure Assuming In-order Issue

- Suppose the instruction is not dispatched by the Issue stage
 - If a RAW hazard exists
 - or if the required FU is busy
- Suppose operands are latched by the functional unit on issue

Can the dispatched instruction cause a *WAR hazard?*

WAW hazard?

Simplifying the Data Structure

- No WAR hazard
 - \Rightarrow no need to keep *src1* and *src2*
- The Issue stage does not dispatch an instruction in case of a WAW hazard
 - ⇒ a register name can occur at most once in the *dest* column
- WP[reg#]: a bit-vector to record the registers for which writes are pending
 - These bits are set to true by the Issue stage and set to false by the WB stage
 - ⇒ Each pipeline stage in the FU's must carry the *dest* field and a flag to indicate if it is valid "the (we, ws) pair"

Scoreboard for In-order Issues

WP[reg#]: a bit-vector to record the registers for which writes are pending.

These bits are set to true by the Issue stage and set to false by the WB stage

Issue checks the instruction (opcode dest src1 src2) against the scoreboard (Busy & WP) to dispatch

FU available? RAW? WAR? WAW?
