# On-Chip Networks II: Router Microarchitecture & Routing

Daniel Sanchez
Computer Science & Artificial Intelligence Lab
M.I.T.

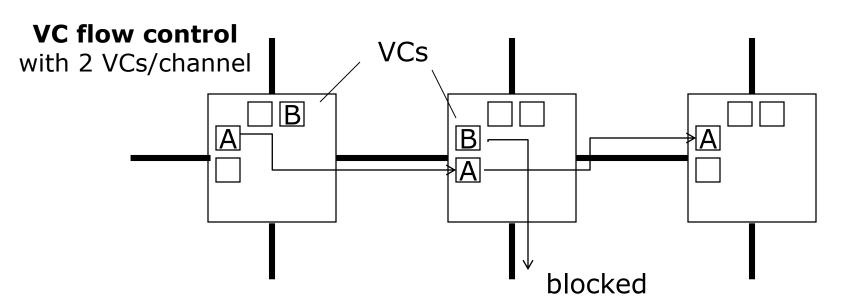

## Recap: Wormhole Flow Control

- Each router manages buffers in flits
- Each packet is sent through output link as soon as possible (without waiting for all its flits to arrive)
- Router buffers are not large enough to hold full packet ->
   on congestion, packet's flits often buffered across routers
- Problem: On congestion, links assigned to a blocked packet cannot be used by other packets

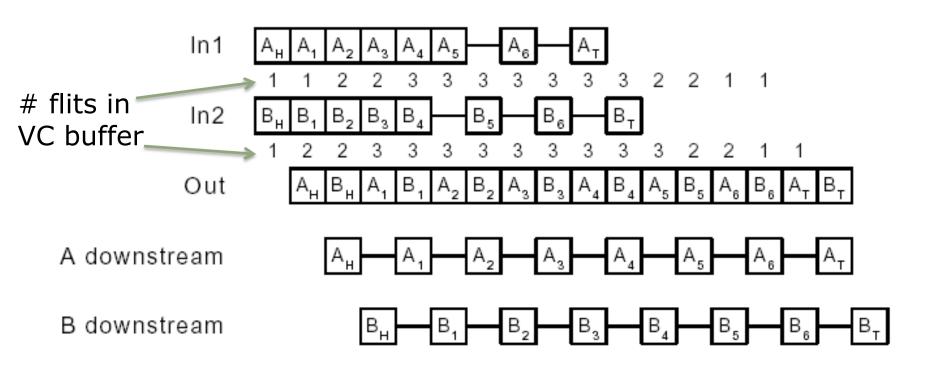

## Recap: Virtual-Channel Flow Control

- When a packet blocks, instead of holding on to channel, hold on to virtual channel
- Virtual channel (VC) = channel state + flit buffers
- Multiple virtual channels reduce blocking
- Ex: Wormhole (=1 VC/channel) vs 2 VCs/channel

# Time-Space View: Virtual-Channel

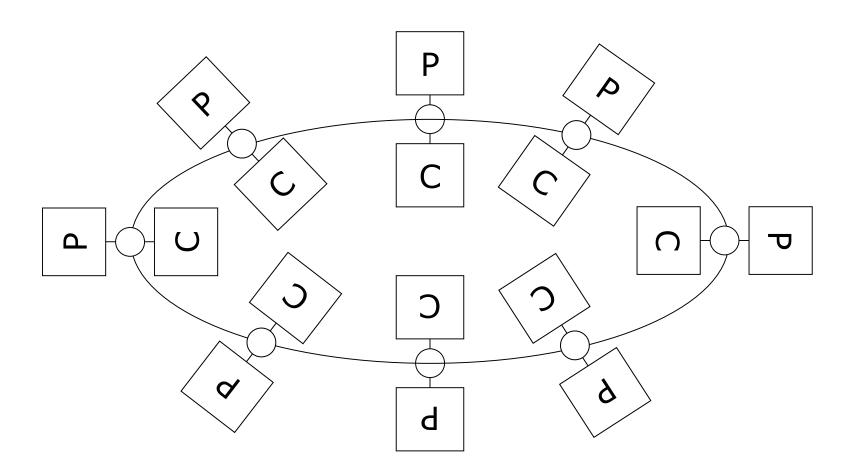

# Interconnection Network Architecture

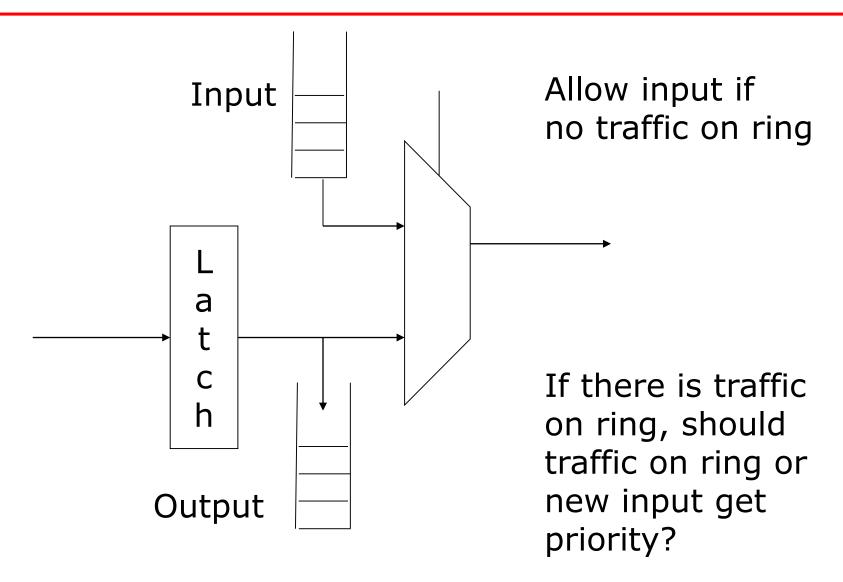

- Topology: How to connect the nodes up? (processors, memories, router line cards, ...)
- Routing: Which path should a message take?
- Flow control: How is the message actually forwarded from source to destination?
- Router microarchitecture: How to build the routers?
- Link microarchitecture: How to build the links?

# Router Microarchitecture

# Ring-based Interconnect

## Ring Stop

## Ring Flow Control: Priorities

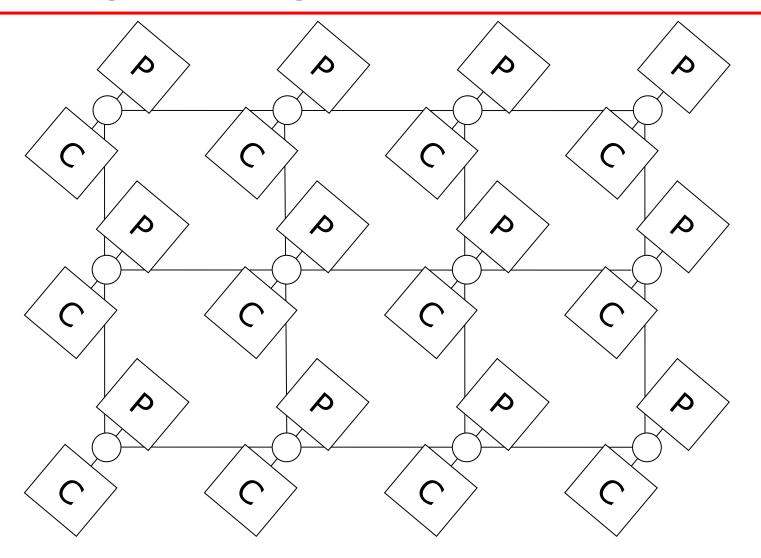

Rotary Rule – <u>traffic in ring has priority</u>

## Ring Flow Control: Bounces

- What if traffic on the ring cannot get delivered, e.g., if output FIFO is full?
- One alternative: Continue on ring (bounce)
- What are the consequences of such bounces?

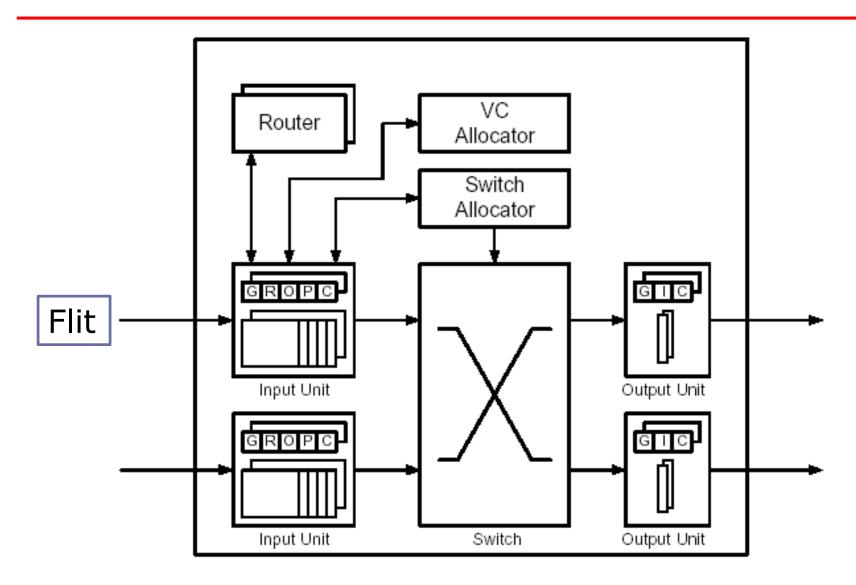

# General Interconnect Tilera, Knights Landing...

### What's In A Router?

- It's a system as well
  - Logic State machines, Arbiters, Allocators
    - Control data movement through router
    - Idle, Routing, Waiting for resources, Active
  - Memory Buffers
    - Store flits before forwarding them
    - SRAMs, registers, processor memory
  - Communication Switches
    - Transfer flits from input to output ports
    - Crossbars, multiple crossbars, fully-connected, bus

## Virtual-channel Router

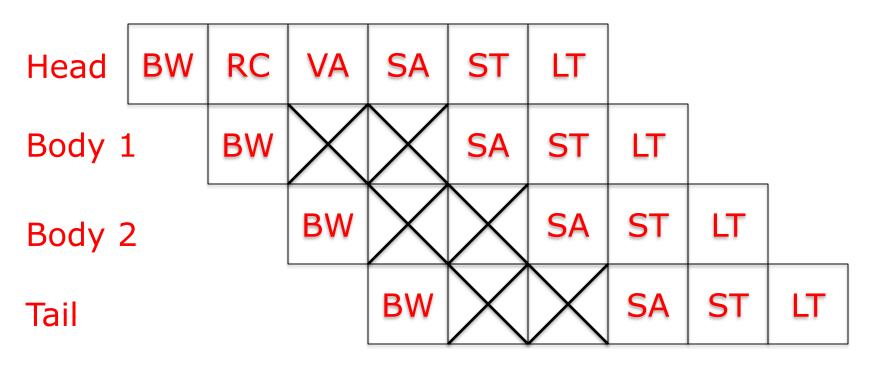

## Router Pipeline vs. Processor Pipeline

- Logical stages:
  - BW
  - RC
  - VA
  - SA
  - BR
  - ST
  - LT
- Different flits go through different stages
- Different routers have different variants
  - E.g. speculation, lookaheads, bypassing
- Different implementations of each pipeline stage

- Logical stages:
  - IF
  - ID
  - EX
  - MEM
  - WB
- Different instructions go through different stages
- Different processors have different variants
  - E.g. speculation, ISA
- Different implementations of each pipeline stage

## Baseline Router Pipeline

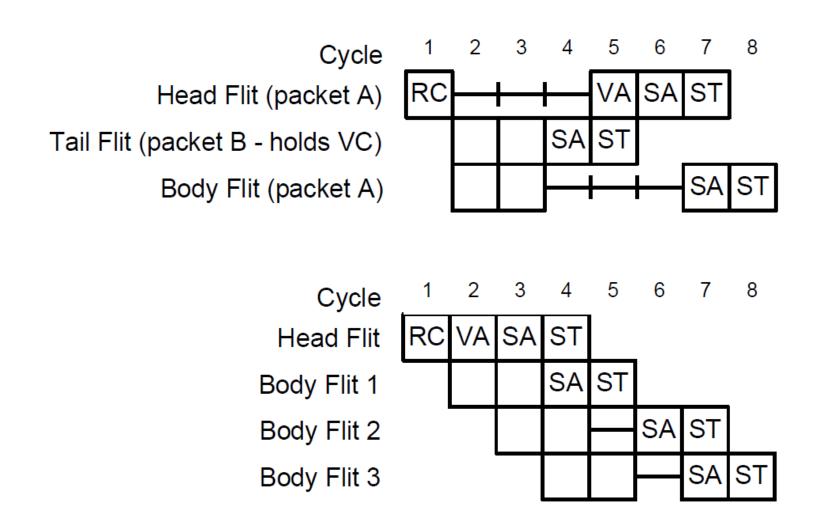

- Route computation performed once per packet
- Virtual channel allocated once per packet
- Body and tail flits inherit this info from head flit

### Allocators In Routers

#### VC Allocator

- Input VCs requesting for a range of output VCs
- Example: A packet of VC0 arrives at East input port. It's destined for west output port, and would like to get any of the VCs of that output port.
- Switch Allocator
  - Input VCs of an input port request for different output ports (e.g., One's going North, another's going West)
- "Greedy" algorithms used for efficiency
- What happens if allocation fails on a given cycle?

## VC & Switch Allocation Stalls

# Pipeline Optimizations: Lookahead Routing [Galles, SGI Spider Chip]

 At current router, perform route computation for next router

- Head flit already carries output port for next router
- RC just has to read output → fast, can be overlapped with BW
- Precomputing route allows flits to compete for VCs immediately after BW
- Routing computation for the next hop (NRC) can be computed in parallel with VA

Or simplify RC (e.g., X-Y routing is very fast)

# Pipeline Optimizations: Speculative Switch Allocation [Peh & Dally, 2001]

- Assume that Virtual Channel Allocation stage will be successful
  - Valid under low to moderate loads
- If both successful, VA and SA are done in parallel

- If VA unsuccessful (no virtual channel returned)
  - Must repeat VA/SA in next cycle
- Prioritize non-speculative SA requests

# Routing

## Properties of Routing Algorithms

#### Deterministic/Oblivious

- route determined by (source, dest),
- not intermediate state (i.e. traffic)

#### Adaptive

route influenced by traffic along the way

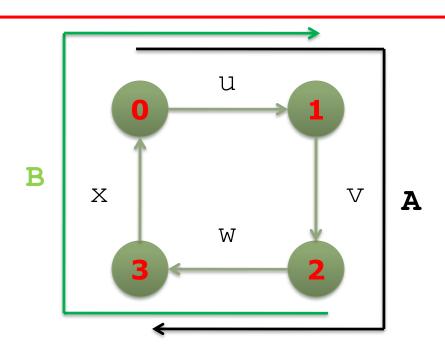

#### Minimal

only selects shortest paths

#### Deadlock-free

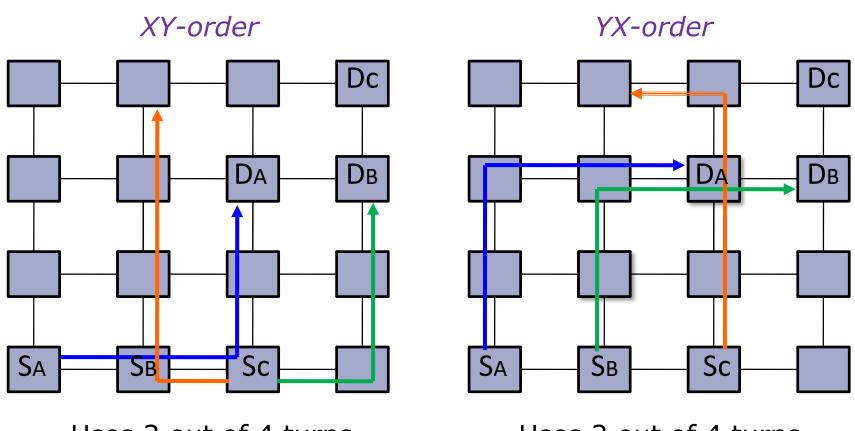

no traffic pattern can lead to a situation where no packets move forward

## Network Deadlock

- Flow A holds <u>u</u> and <u>v</u> but cannot make progress until it acquires channel <u>w</u>
- Flow B holds channels <u>w</u> and <u>x</u> but cannot make progress until it acquires channel <u>u</u>

## Dimension-Order Routing

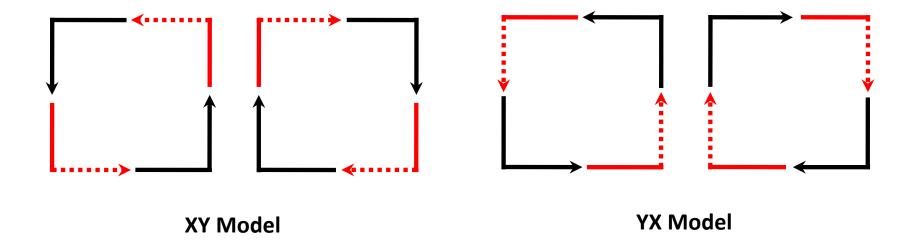

Uses 2 out of 4 turns

Uses 2 out of 4 turns

XY is deadlock free, YX is deadlock free, what about XY+YX?

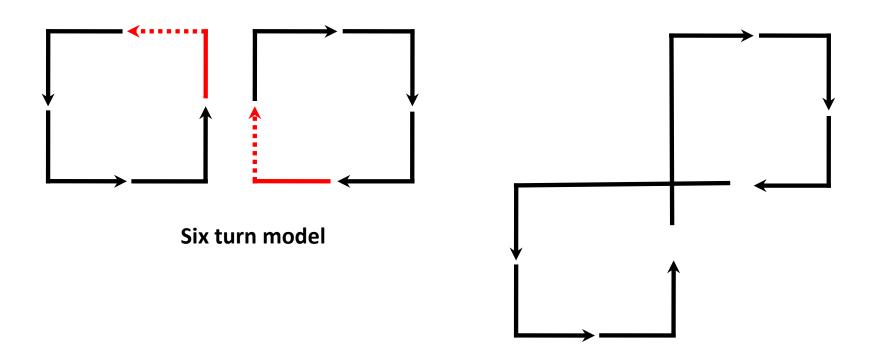

### DOR - Turns allowed

- One way of looking at whether a routing algorithm is deadlock-free is to look at the turns allowed
- Deadlocks may occur if turns can form a cycle

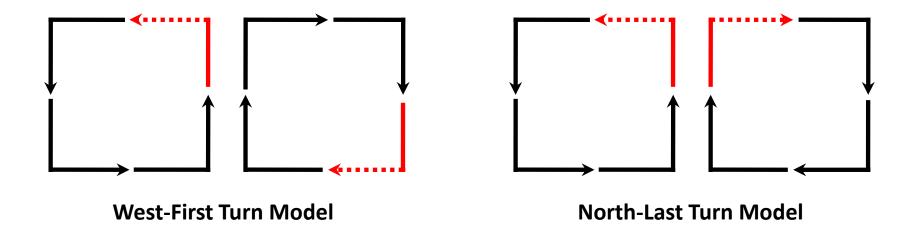

# Allowing more turns

 Allowing more turns may allow adaptive routing, but also deadlock

## Turn Model [Glass and Ni, 1994]

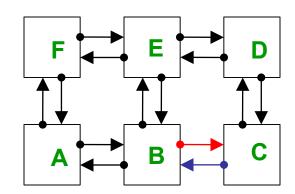

- A systematic way of generating deadlock-free routes with small number of <u>prohibited turns</u>
- Deadlock-free if routes conform to at least ONE of the turn models (acyclic channel dependence graph)

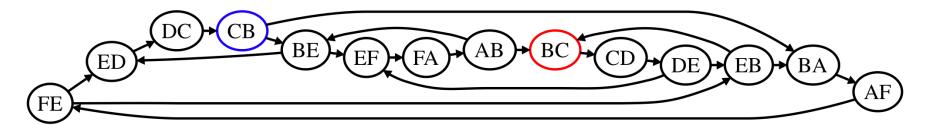

## 2-D Mesh and CDG

Can create a channel dependency graph (CDG) of the network.

Vertices in the CDG represent network *links* 

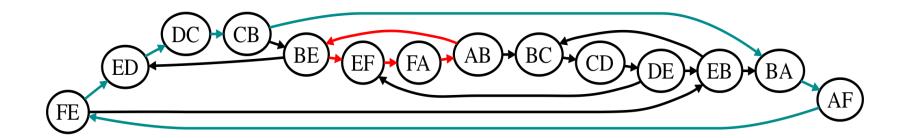

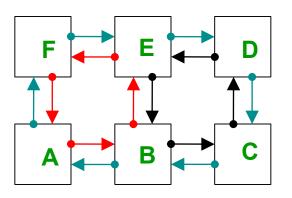

Disallowing 180° turns, e.g., AB → BA

## Cycles in CDG

The channel dependency graph D derived from the network topology may contain many cycles

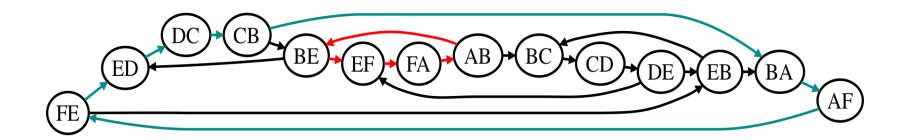

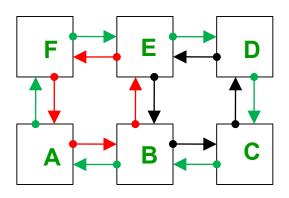

Flow routed through links AB, BE, EF Flow routed through links EF, FA, AB Deadlock!

# Key Insight

If routes of flows conform to acyclic CDG, then there will be no possibility of deadlock!

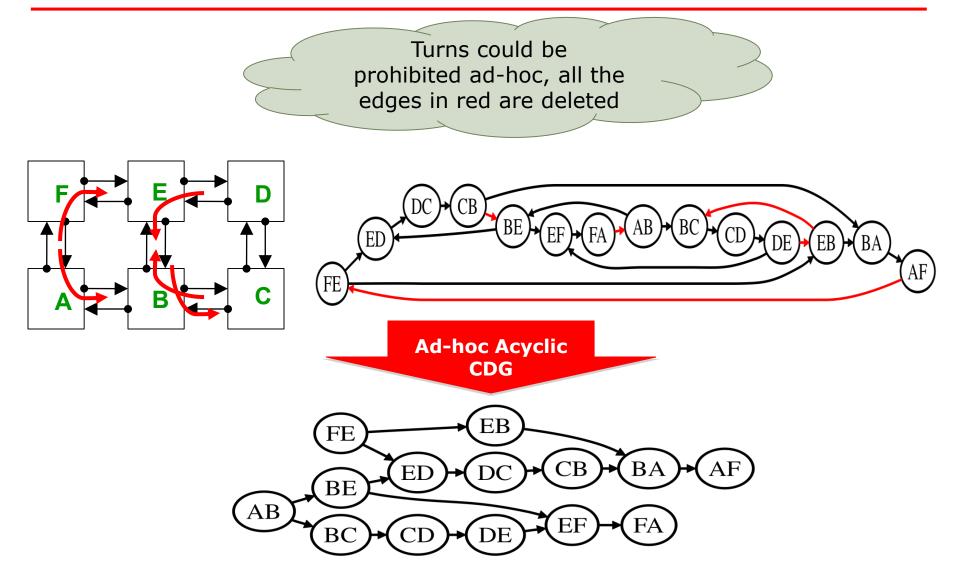

Disallow/Delete certain edges in CDG

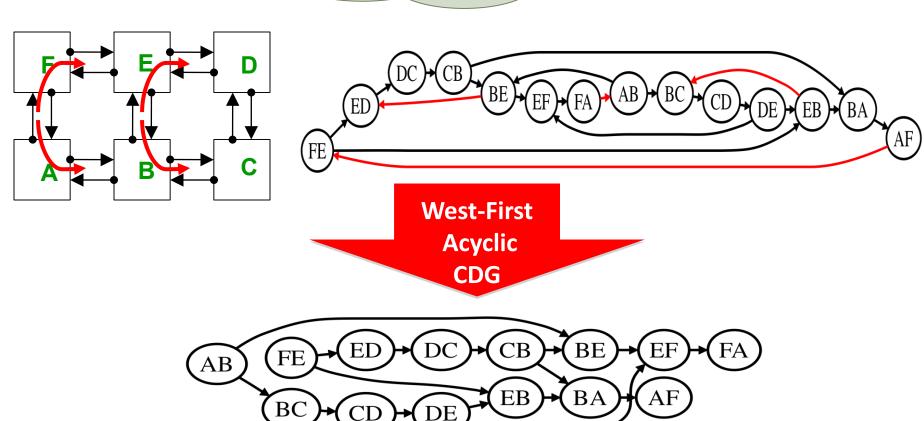

Edges in CDG correspond to turns in network!

## Acyclic CDG → Deadlock-free routes

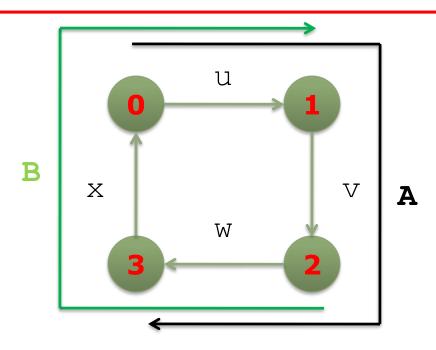

## West-first → Deadlock-free routes

Per the West-First prohibited turns, all the edges in red are deleted

## Resource Conflicts → Deadlock

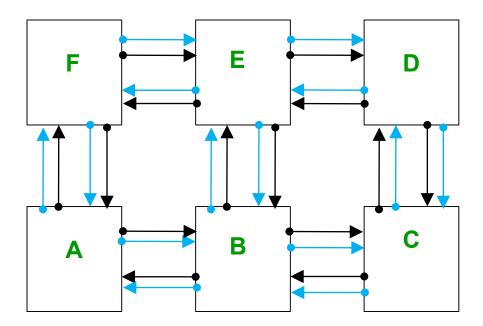

Routing deadlocks in wormhole routing result from Structural hazard at router resources, e.g., buffers.

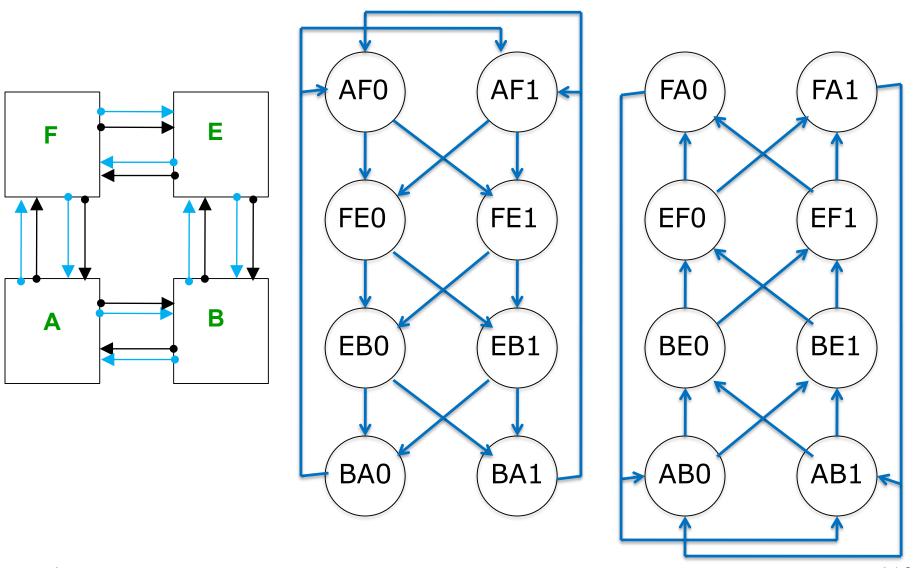

How can structural hazards be avoided?

## Virtual Channels

 Virtual channels can be used to avoid deadlock by restricting VC allocation

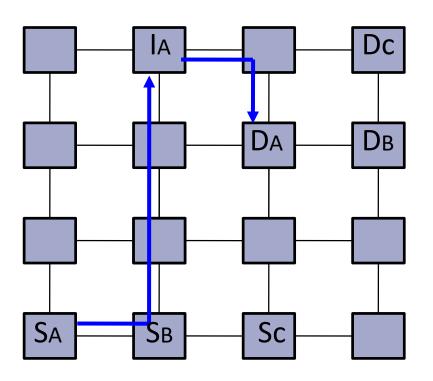

## CDG and Virtual Channels

# Randomized Routing: Valiant

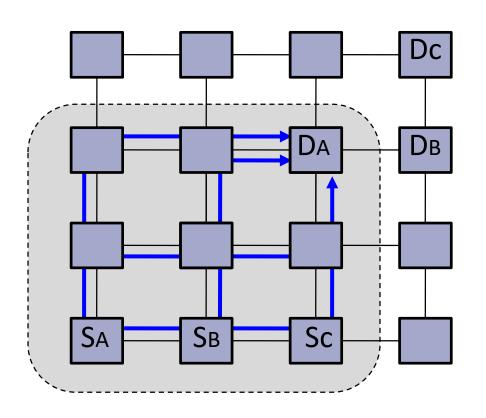

Route each packet through a randomly chosen intermediate node

A packet, going from node SA to node DA, is first routed from SA to a randomly chosen intermediate node IA, before going from IA to final destination DA.

It helps load-balance the network and has a good worst-case performance at the expense of <u>locality</u>.

# ROMM: Randomized, Oblivious Multi-phase Minimal Routing

To retain locality, choose intermediate node in the minimal quadrant

Equivalent to randomly selecting among the various minimal paths from source to destination

# Thank you!
