In-order: 1 (2,1) . . . . . 2 3 4 4 3 5 . . . 5 6 6

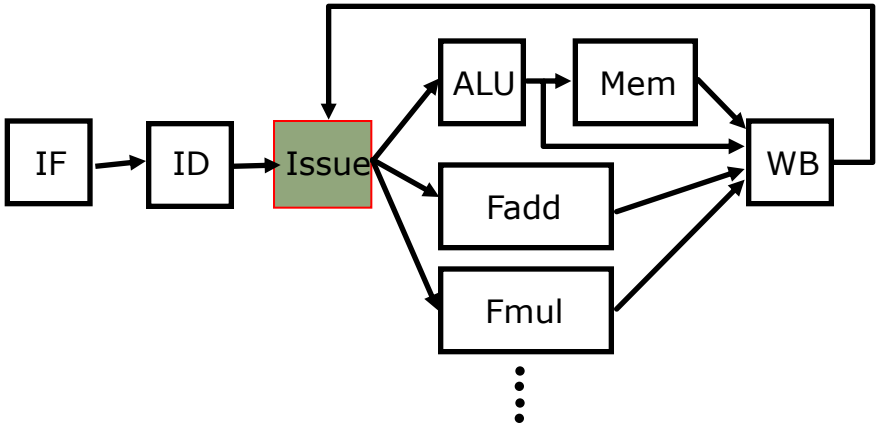
In-order restriction prevents instruction 4 from being dispatched

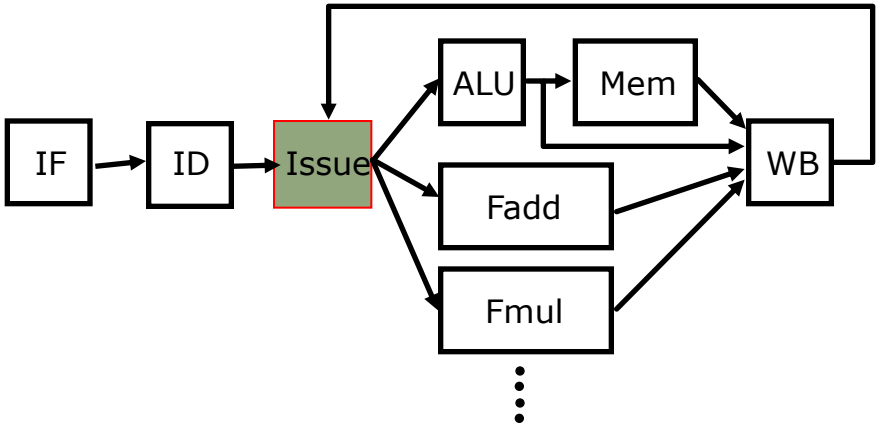
Out-of-Order Issue

How can we address the delay caused by a RAW dependence associated with the next in-order instruction?



Out-of-Order Issue

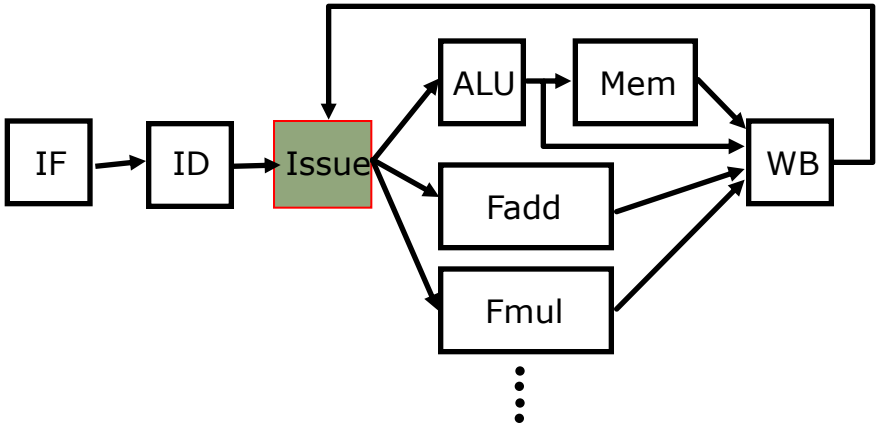
How can we address the delay caused by a RAW dependence associated with the next in-order instruction?



Find something else to do!

Out-of-Order Issue

How can we address the delay caused by a RAW dependence associated with the next in-order instruction?

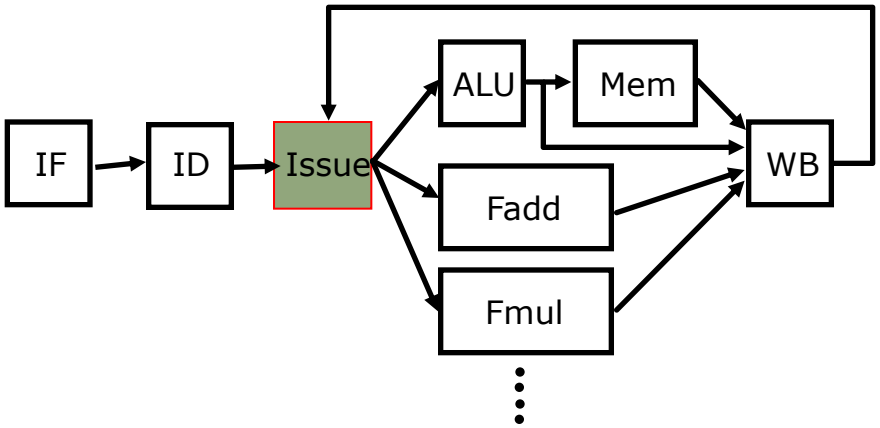


Find something else to do!

- Issue stage buffer holds multiple instructions waiting to issue.

Out-of-Order Issue

How can we address the delay caused by a RAW dependence associated with the next in-order instruction?

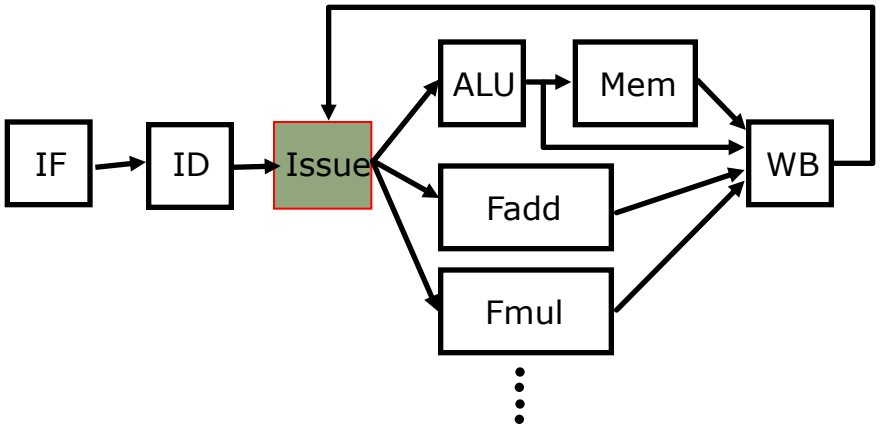


Find something else to do!

- Issue stage buffer holds multiple instructions waiting to issue.
- Decode adds next instruction to buffer if there is space and the instruction does not cause a WAR or WAW hazard.

Out-of-Order Issue

How can we address the delay caused by a RAW dependence associated with the next in-order instruction?



Find something else to do!

- Issue stage buffer holds multiple instructions waiting to issue.
- Decode adds next instruction to buffer if there is space and the instruction does not cause a WAR or WAW hazard.
- Can issue any instruction in buffer whose RAW hazards are satisfied *(for now at most one dispatch per cycle).* A writeback (WB) may enable more instructions.

In-Order Issue Limitations: *an example*

					latency
1	LD	F2,	34(R2)		*1*
2	LD	F4,	45(R3)		*long*

How many Instructions can be in the pipeline

Which feature of an ISA limits the number of instructions in the pipeline?

_____

How many Instructions can be in the pipeline

Which feature of an ISA limits the number of instructions in the pipeline?

Number of Registers

How many Instructions can be in the pipeline

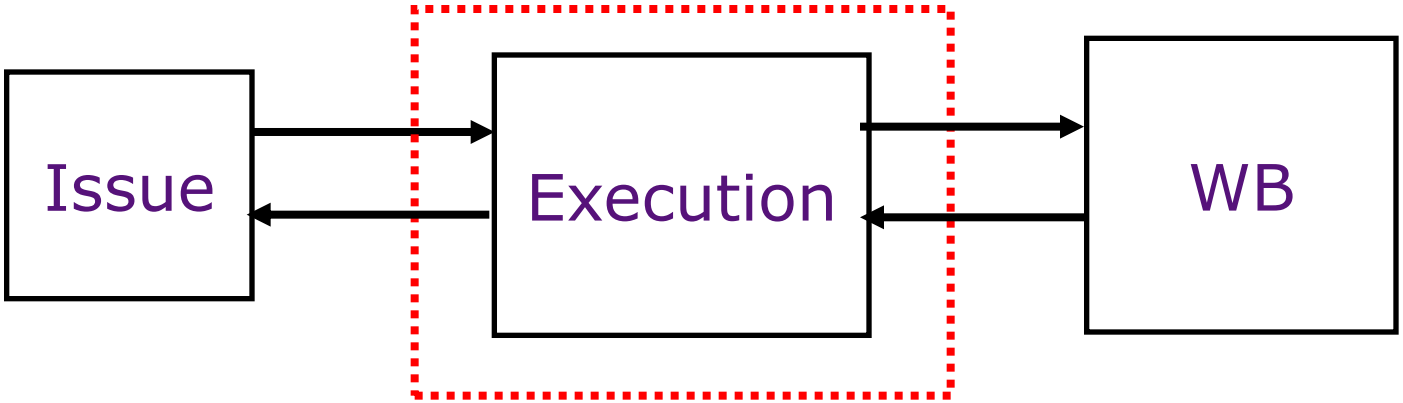
Which feature of an ISA limits the number of instructions in the pipeline?

Number of Registers

Out-of-order dispatch by itself does not provide any significant performance improvement !

Little's Law

Throughput (T) = Number in Flight (N) / Latency (L)



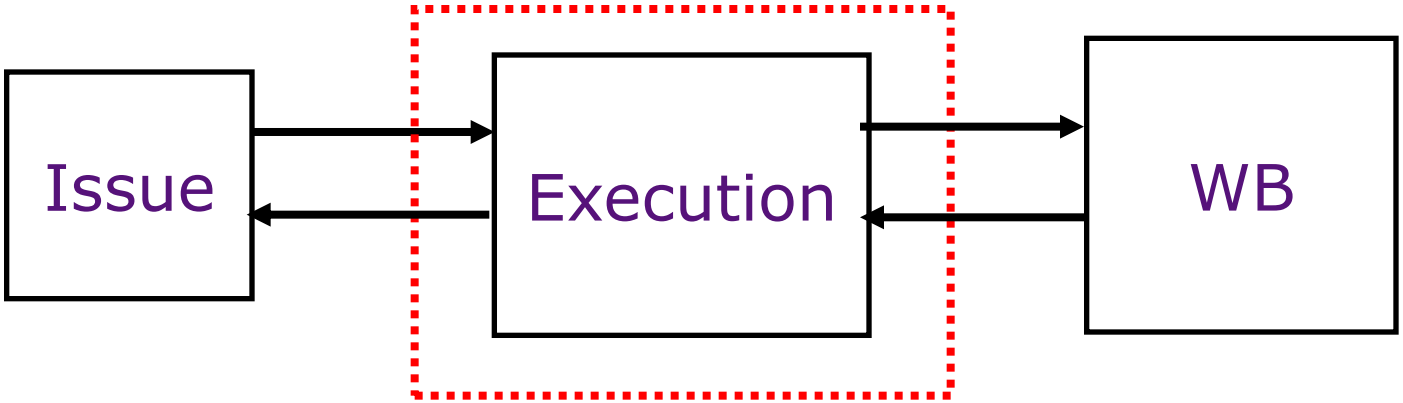
Example:

4 floating point registers
8 cycles per floating point operation

⇒

Little's Law

Throughput (T) = Number in Flight (N) / Latency (L)



Example:

4 floating point registers
8 cycles per floating point operation

⇒ *½ issues per cycle!*

Overcoming the Lack of Register Names

Floating Point pipelines often cannot be kept filled with small number of registers.

IBM 360 had only 4 Floating Point Registers

Can a microarchitecture use more registers than specified by the ISA without loss of ISA compatibility ?

Overcoming the Lack of Register Names

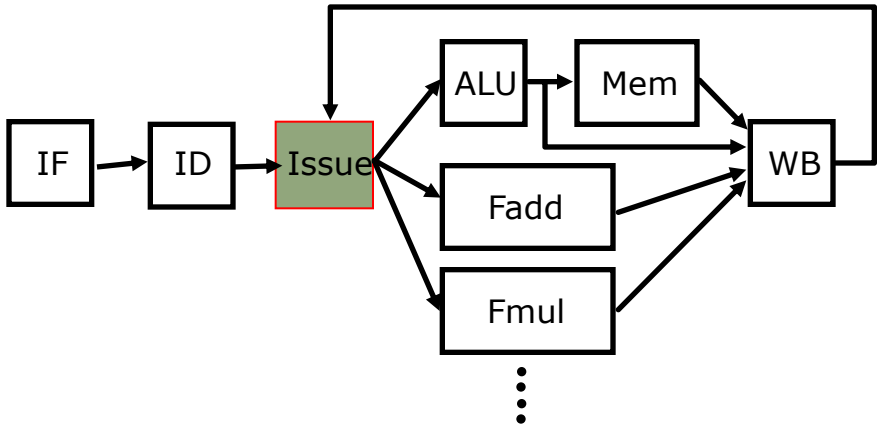
Floating Point pipelines often cannot be kept filled with small number of registers.

IBM 360 had only 4 Floating Point Registers

Can a microarchitecture use more registers than specified by the ISA without loss of ISA compatibility ?

Yes, Robert Tomasulo of IBM suggested an ingenious solution in 1967 based on on-the-fly *register renaming*

Register Renaming



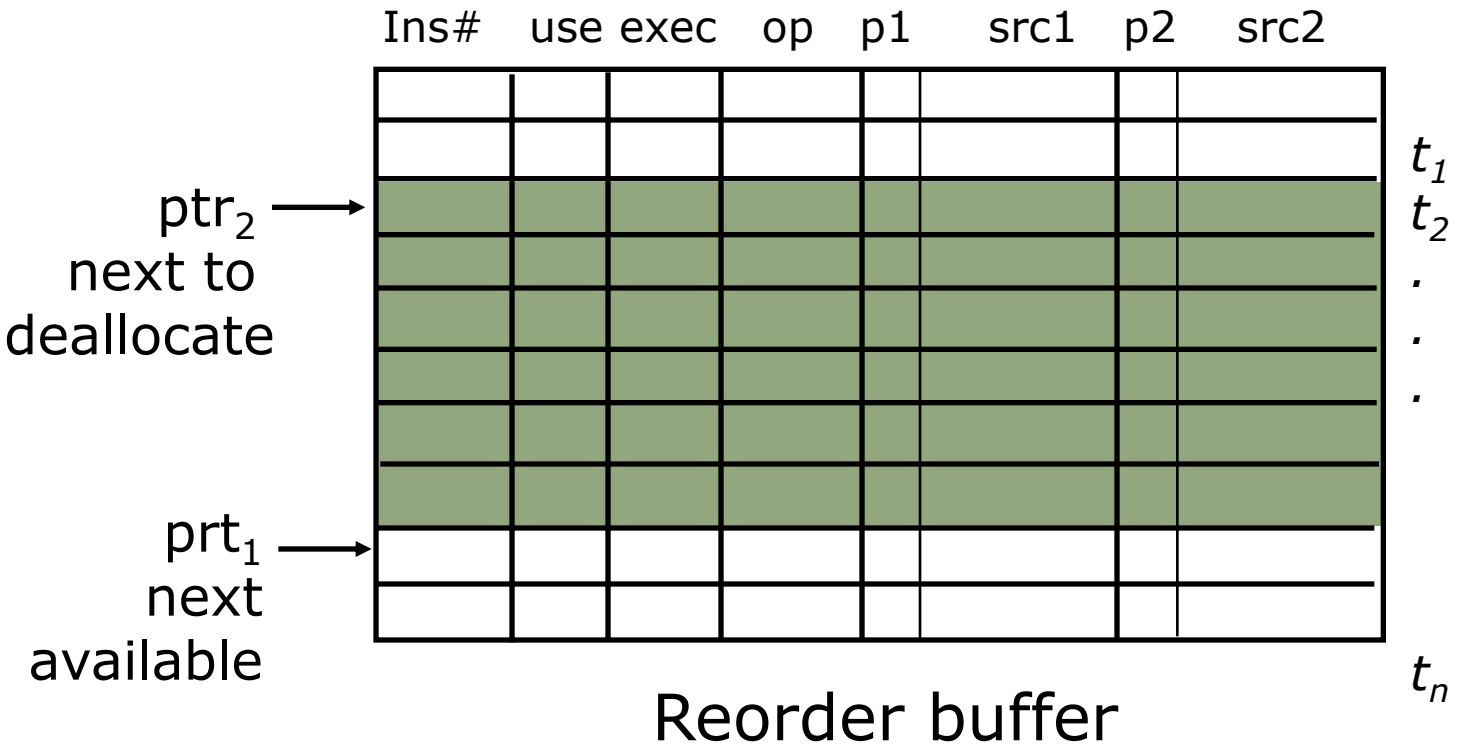
- Decode does register renaming and adds instructions to the issue stage reorder buffer (ROB)

  ⇒ renaming makes WAR or WAW hazards impossible

- Any instruction in ROB whose RAW hazards have been satisfied can be dispatched.

  ⇒ Out-of-order or dataflow execution

Dataflow execution



Instruction slot is candidate for execution when:

- It holds a valid instruction ("use" bit is set)
- It has not already started execution ("exec" bit is clear)
- Both operands are available (p1 and p2 are set)

Renaming & Out-of-order Issue

An example

  Whenever an instruction completes

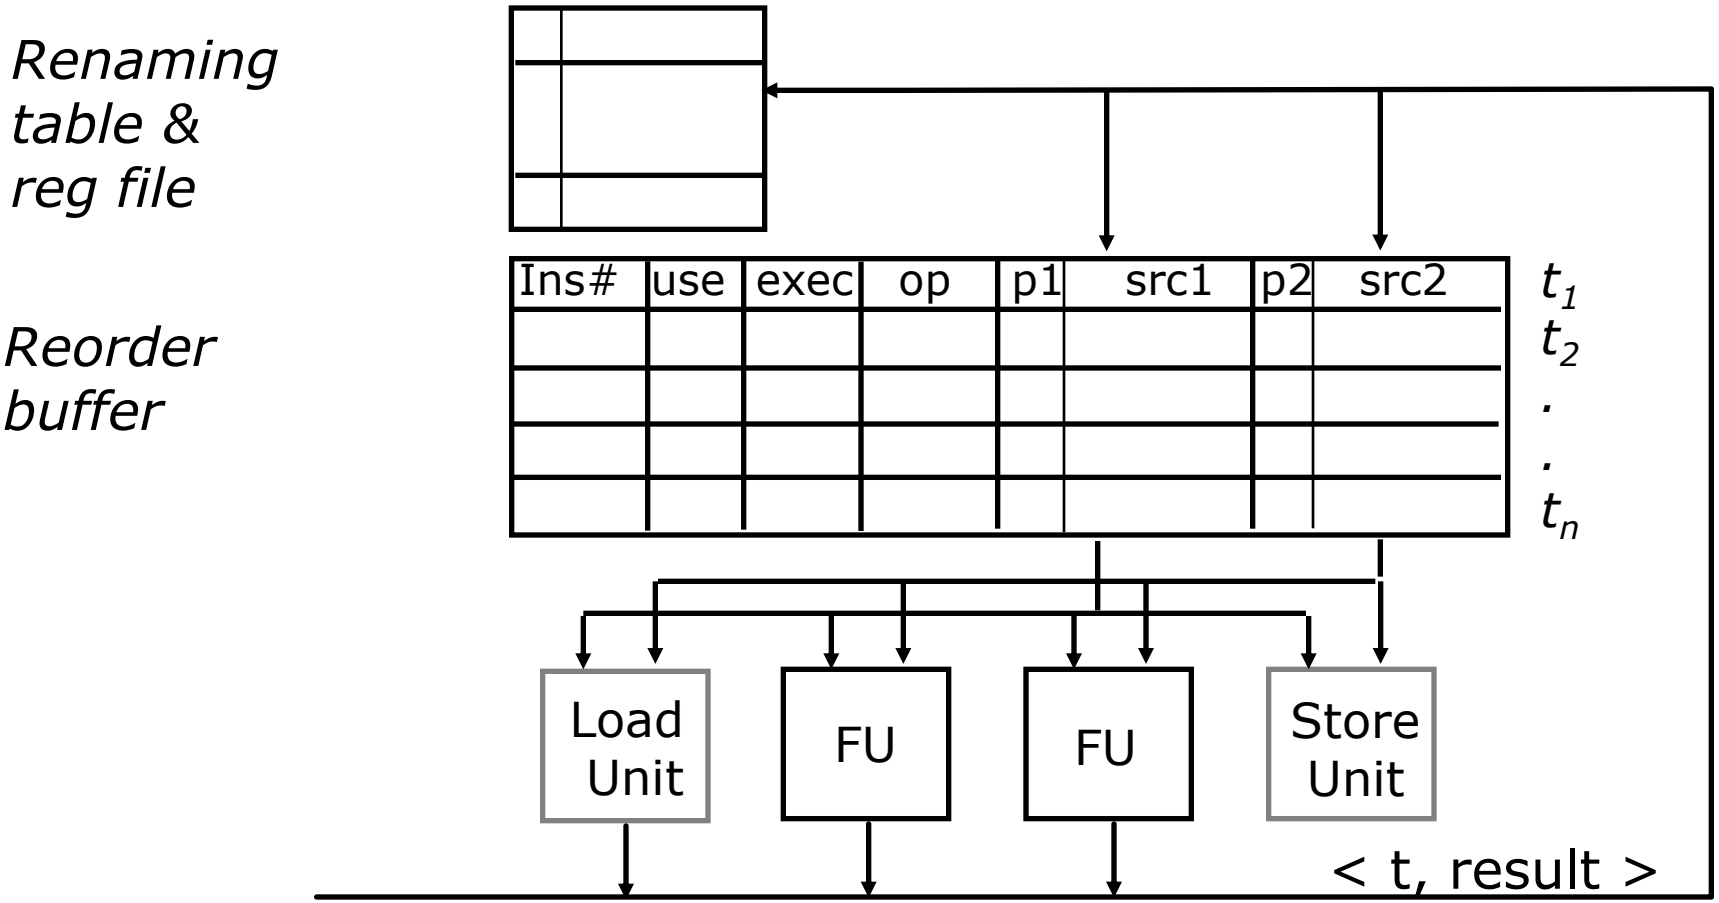
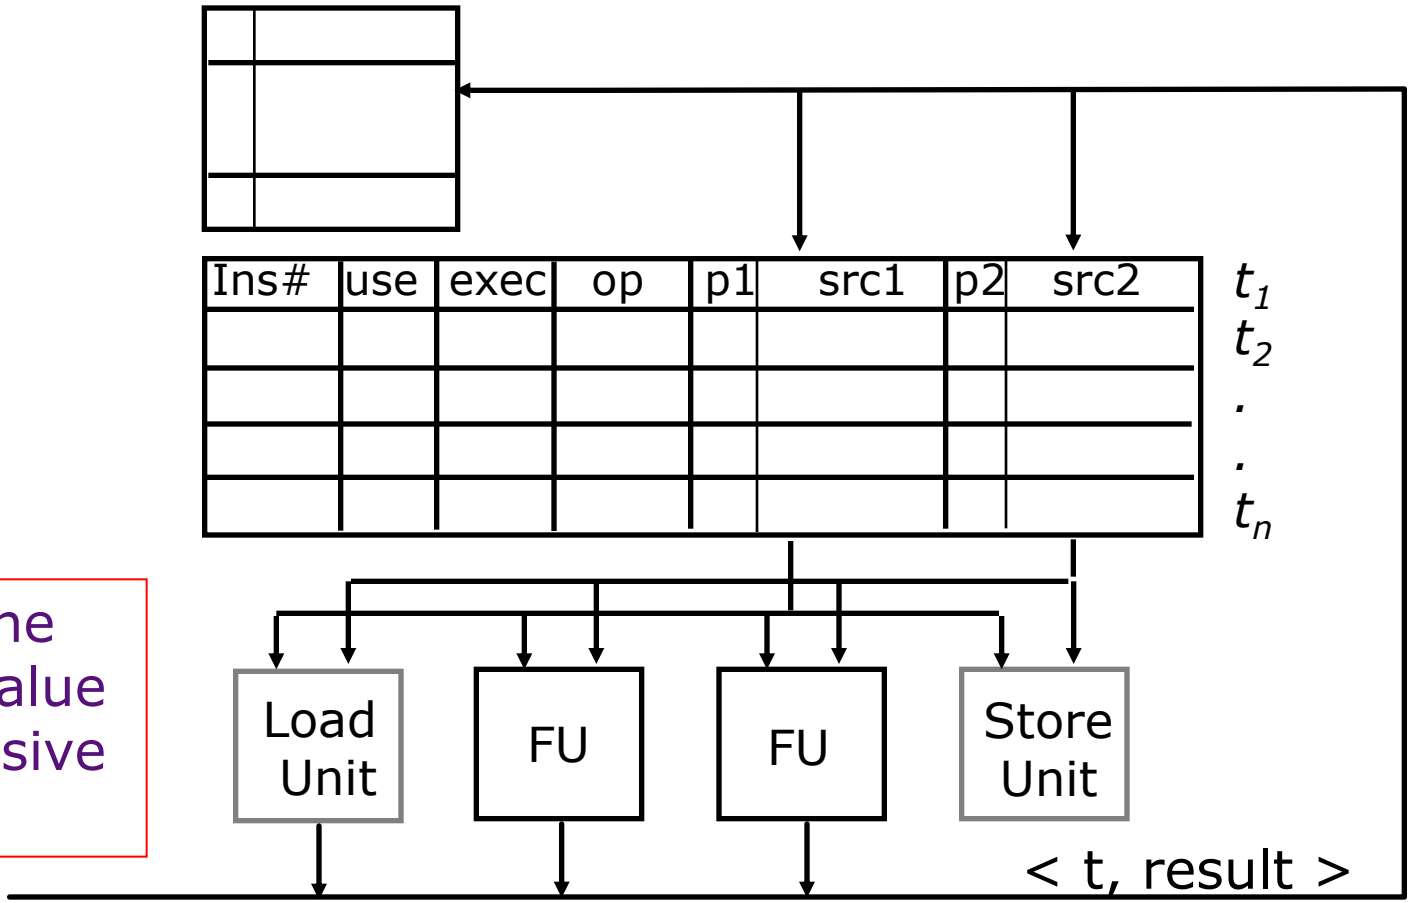
Data-Driven Execution



- Instruction template (i.e., tag t) is allocated by the Decode stage, which also stores the tag in the reg file
- When an instruction completes, its tag is deallocated

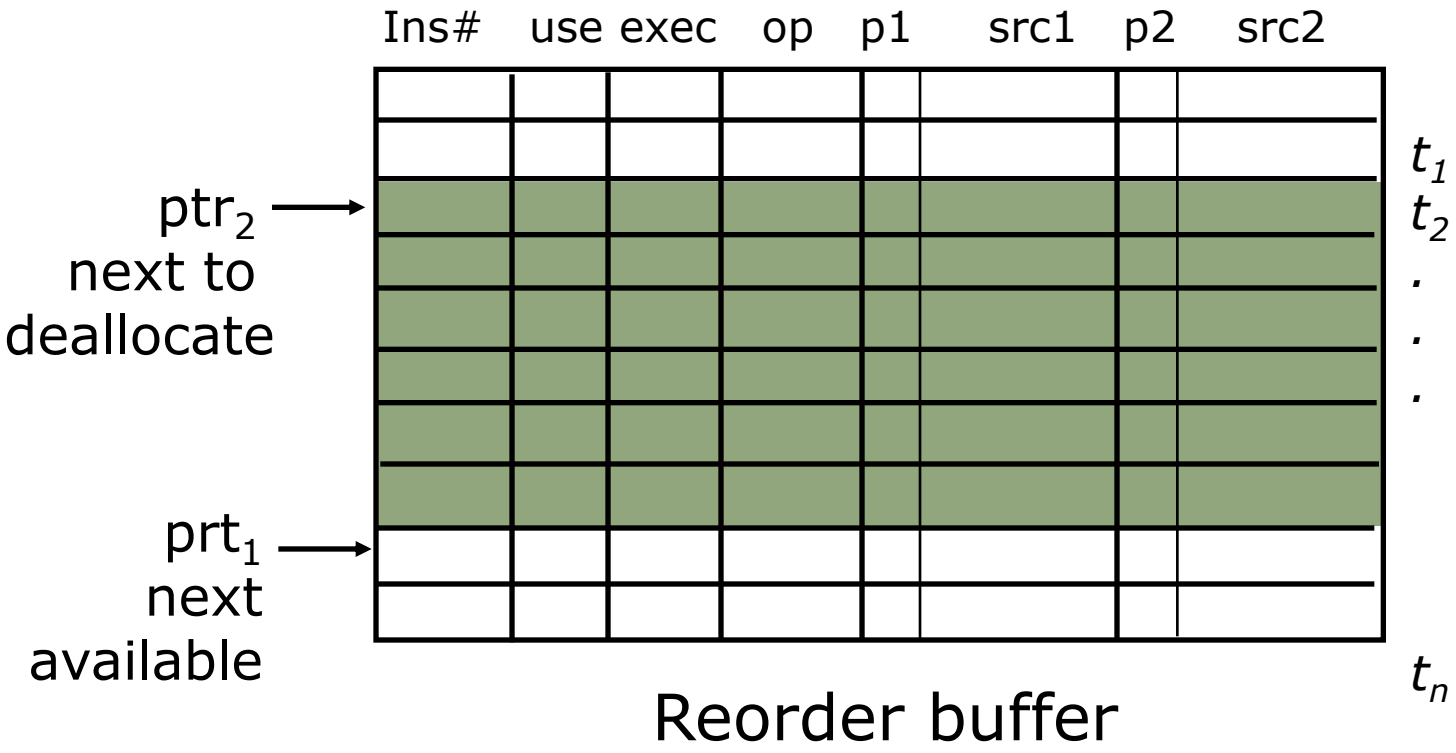
Data-Driven Execution



Replacing the tag by its value is an expensive operation

- Instruction template (i.e., tag t) is allocated by the Decode stage, which also stores the tag in the reg file
- When an instruction completes, its tag is deallocated

Simplifying Allocation/Deallocation

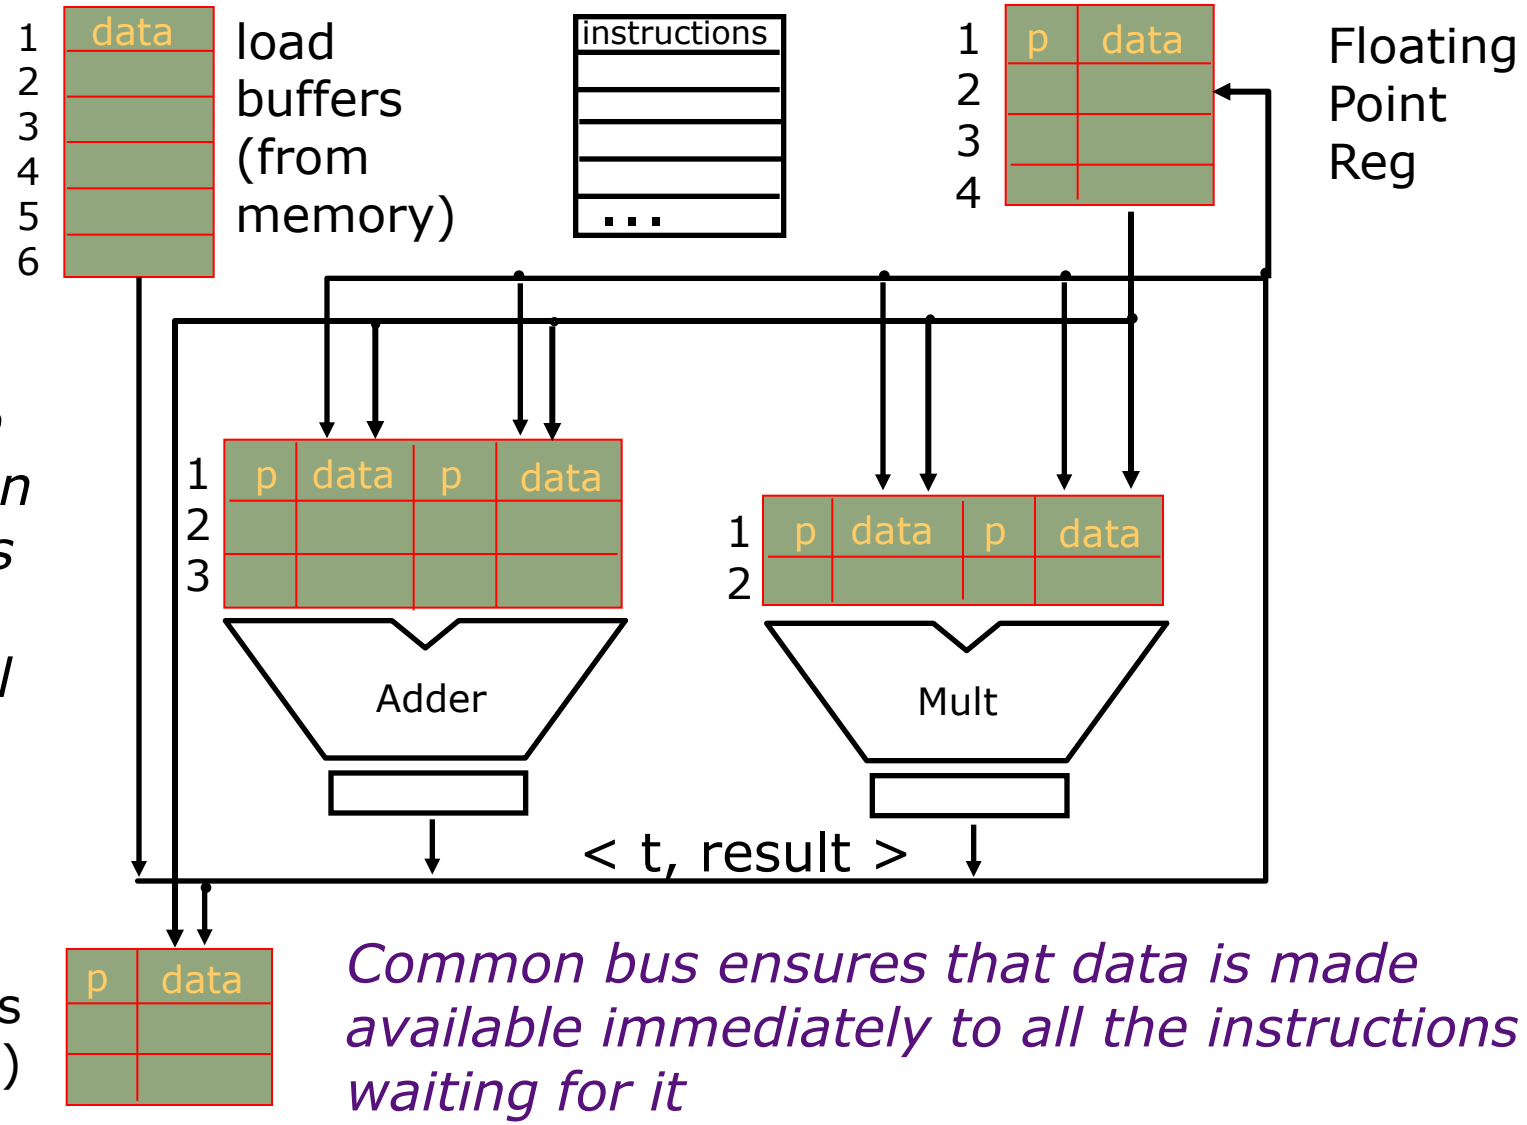


Instruction buffer is managed circularly

- "exec" bit is set when instruction begins execution
- When an instruction completes its "use" bit is marked free
- ptr_2 is incremented only if the "use" bit is marked free

IBM 360/91 Floating Point Unit

R. M. Tomasulo, 1967



Common bus ensures that data is made available immediately to all the instructions waiting for it

Effectiveness?

Renaming and Out-of-order execution was first implemented in 1969 in IBM 360/91 but did not show up in the subsequent models until mid-nineties.

Why?

Effectiveness?

Renaming and Out-of-order execution was first implemented in 1969 in IBM 360/91 but did not show up in the subsequent models until mid-nineties.

Why?

1. Effective on a very small class of programs

Effectiveness?

Renaming and Out-of-order execution was first implemented in 1969 in IBM 360/91 but did not show up in the subsequent models until mid-nineties.

Why?

1. Effective on a very small class of programs
2. Did not address the memory latency problem which turned out be a much bigger issue than FU latency
3. Made exceptions imprecise

More on this in the next lecture

Precise Exceptions

Exceptions are relatively unlikely events that need special processing, but where adding explicit control flow instructions is not desired, e.g., divide by 0, page fault

Exceptions can be viewed as an implicit conditional subroutine call that is inserted between two instructions.

Therefore, it must appear as if the exception is taken between two instructions (say I_i and I_{i+1})

- the effect of all instructions up to and including I_i is complete
- no effect of any instruction after I_i has taken place

The handler either aborts the program or restarts it at I_{i+1} .

  - fetch at handler PC

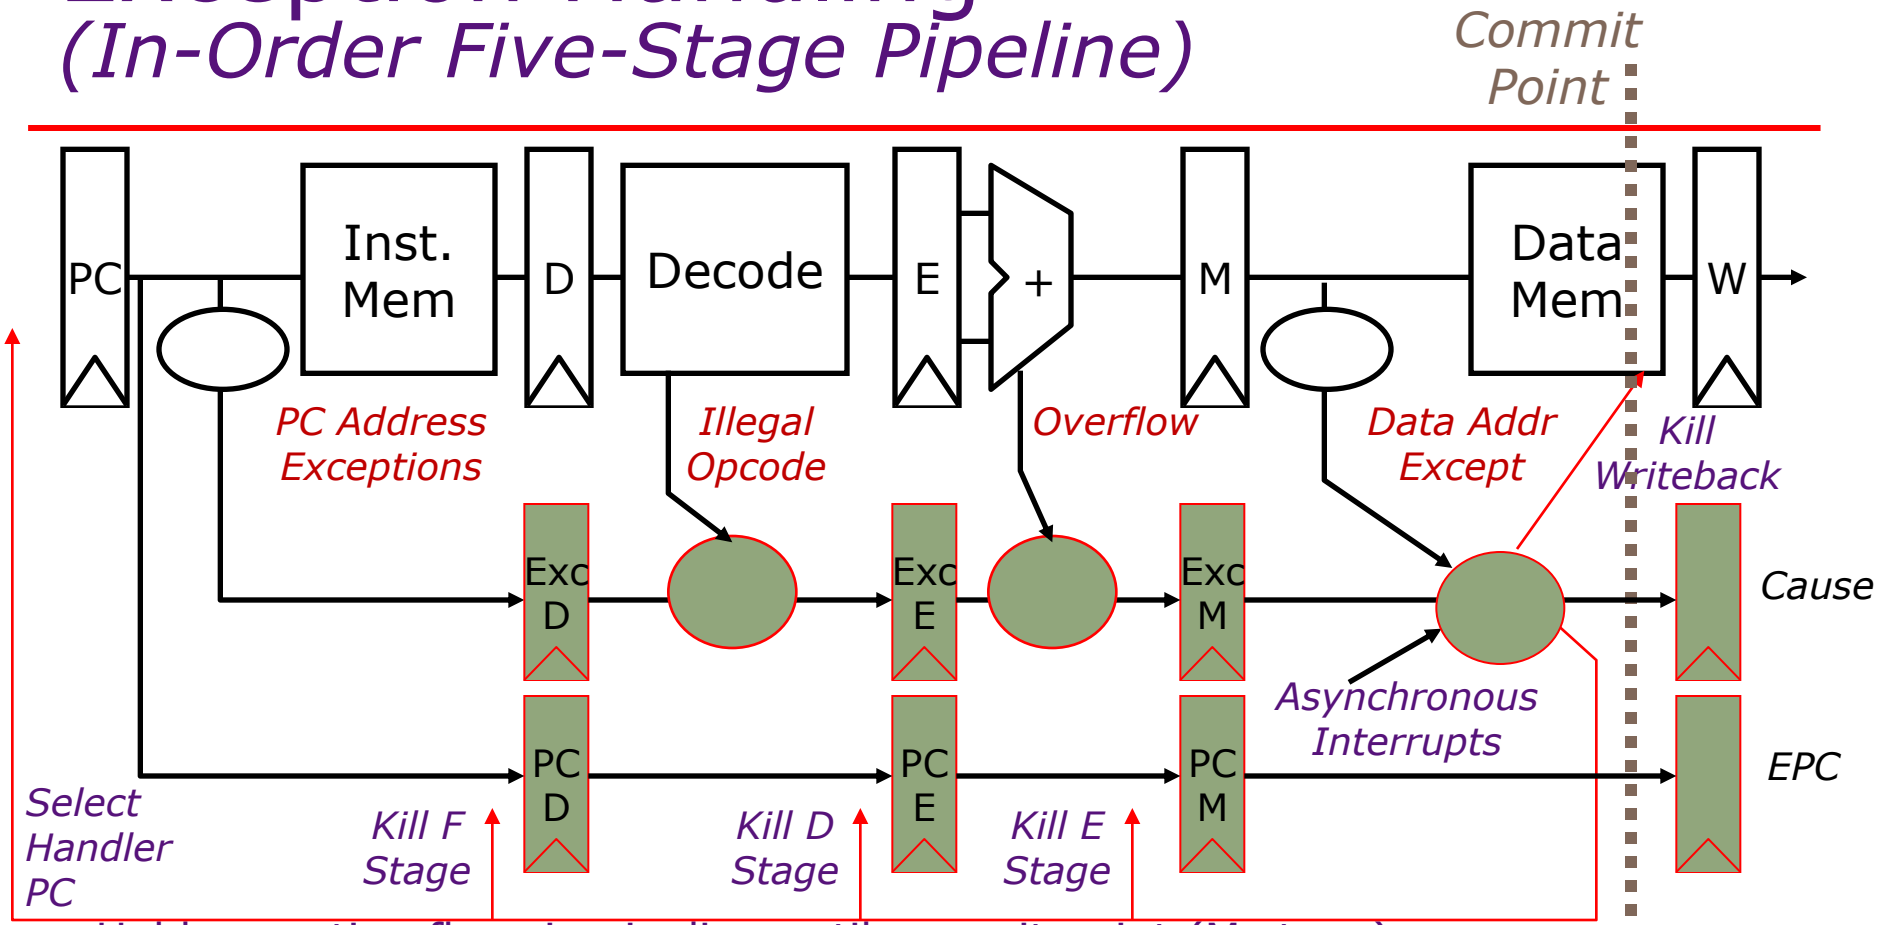
Inject external interrupts at commit point

Exception Handling
(In-Order Five-Stage Pipeline)

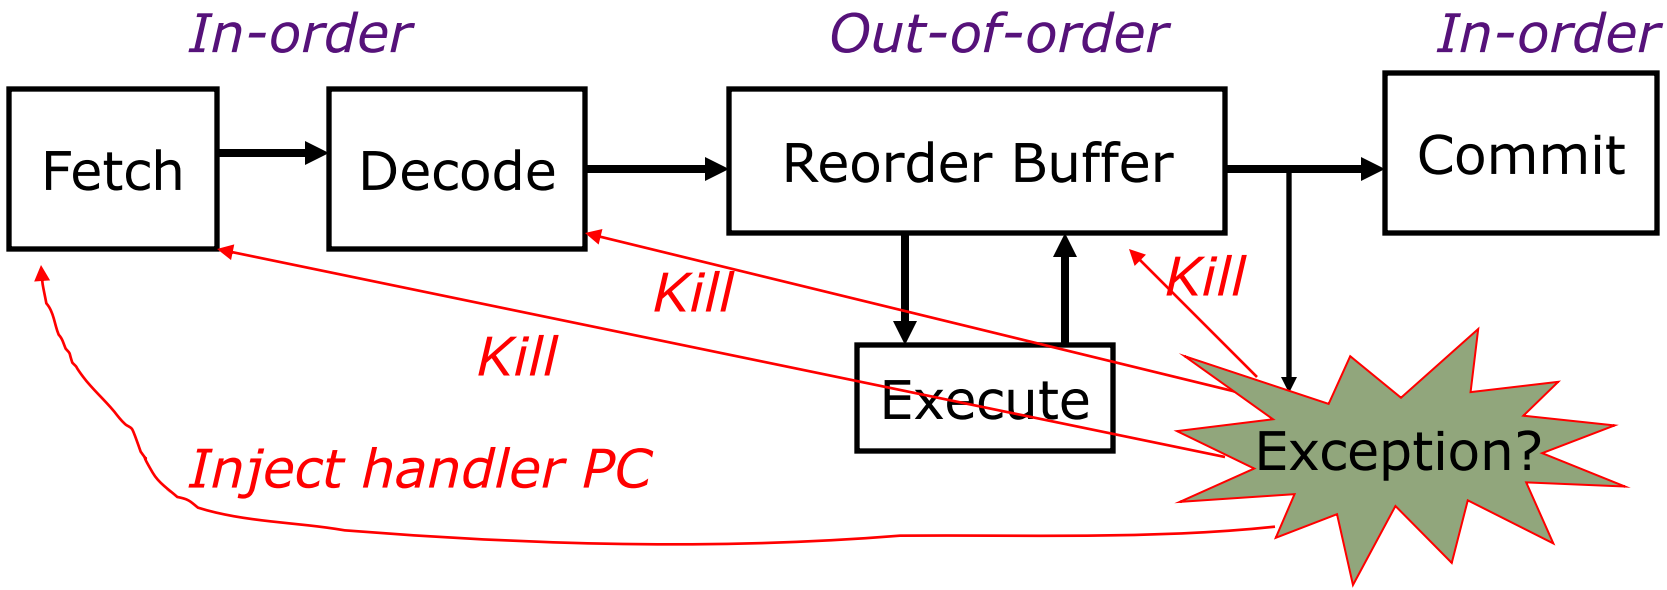


Hold exception flags in pipeline until commit point (M stage)

- If exception at commit:
  - update Cause/EPC registers
  - kill all stages
  - fetch at handler PC

Inject external interrupts at commit point

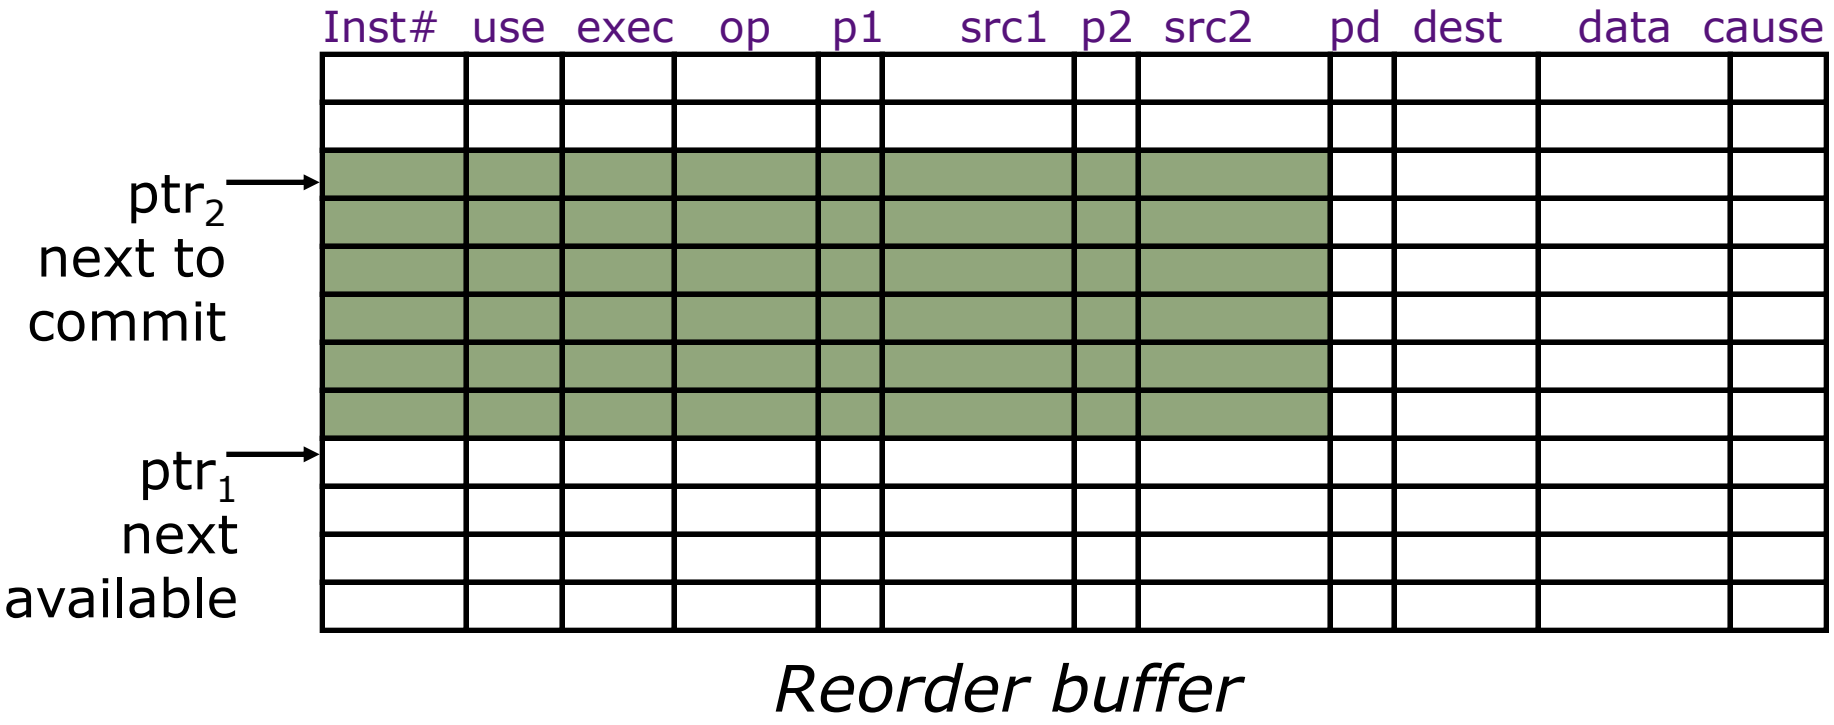
In-Order Commit for Precise Exceptions



- Instructions fetched and decoded into instruction reorder buffer in-order
- Execution is out-of-order (⇒ out-of-order completion)
- *Commit* (write-back to architectural state, i.e., regfile & memory, is in-order

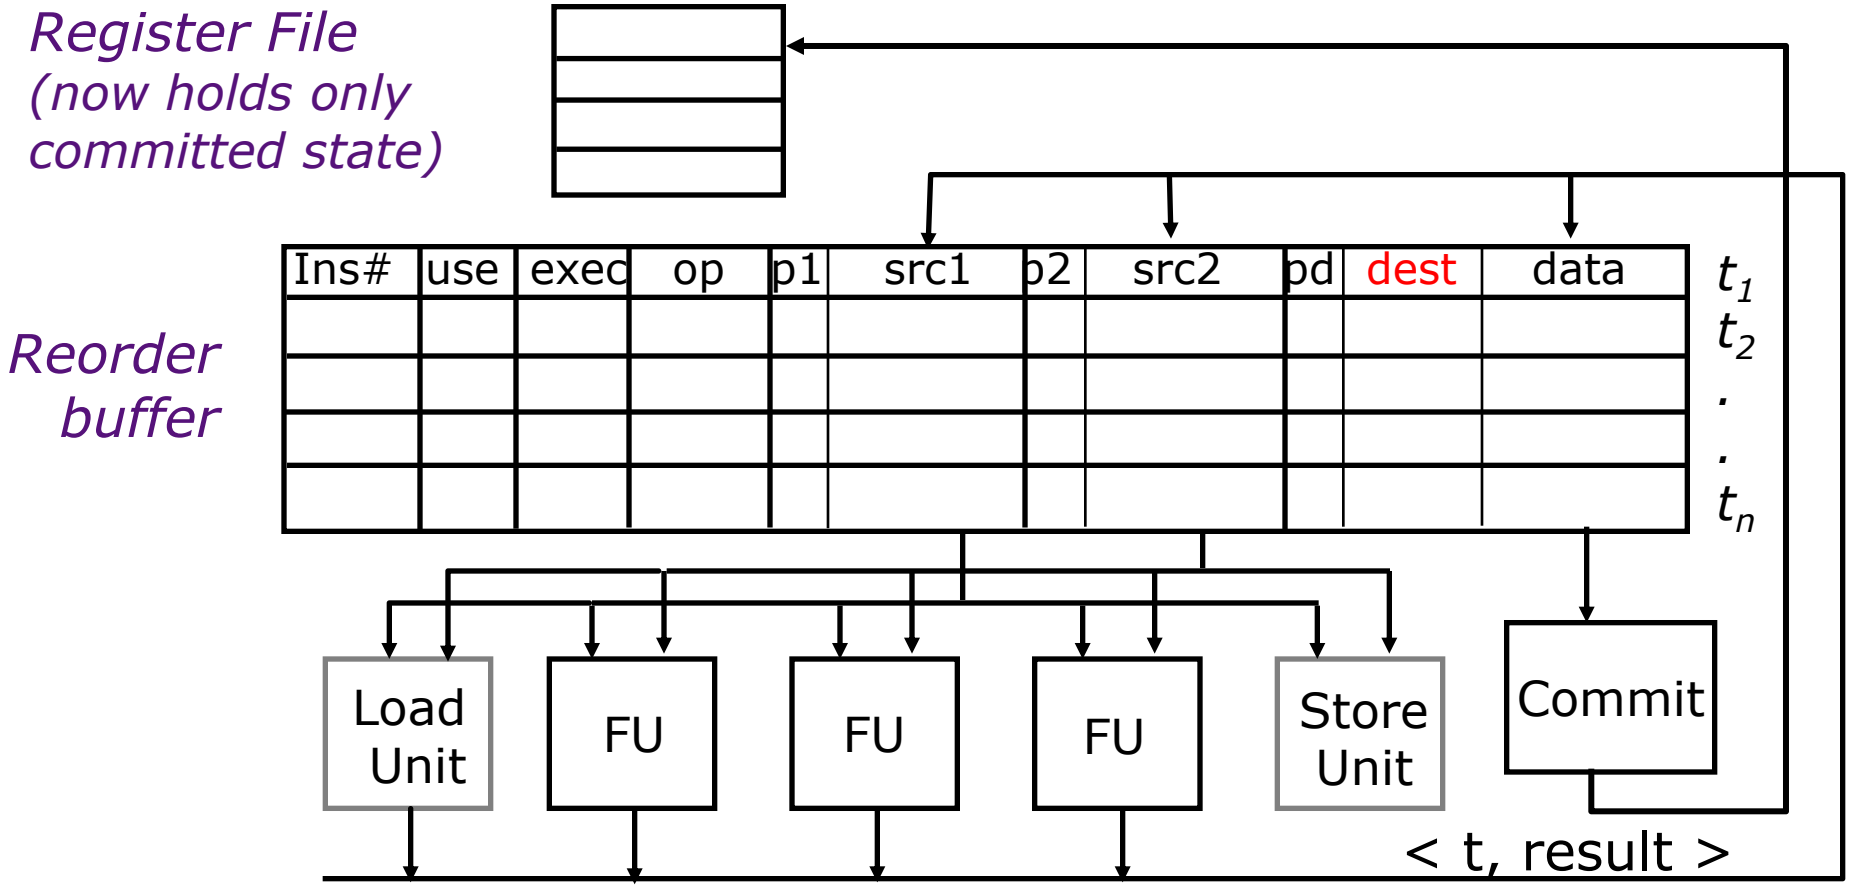
Temporary storage needed to hold results before commit (shadow registers and store buffers)

Extensions for Precise Exceptions



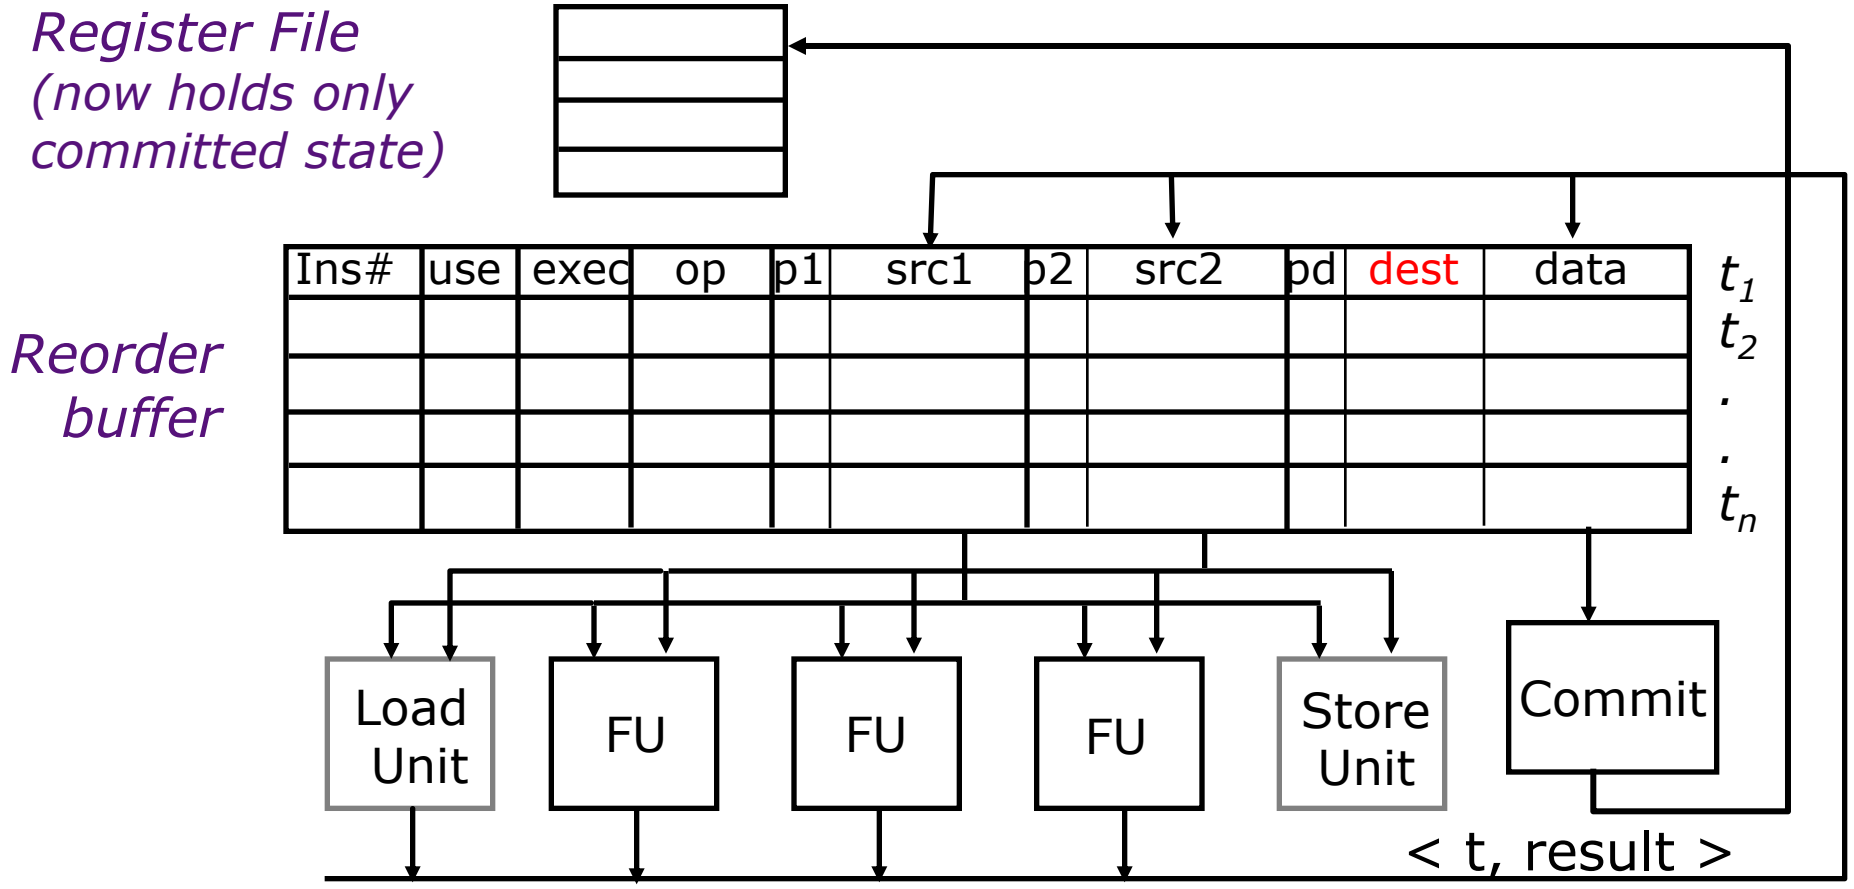
- add <pd, dest, data, cause> fields in the instruction template
- commit instructions to reg file and memory in program order ⇒ buffers can be maintained circularly
- on exception, clear reorder buffer by resetting $ptr_1 = ptr_2$
  (stores must wait for commit before updating memory)

Rollback and Renaming



Register file does not contain renaming tags any more.
How does the decode stage find the tag of a source register?

Rollback and Renaming

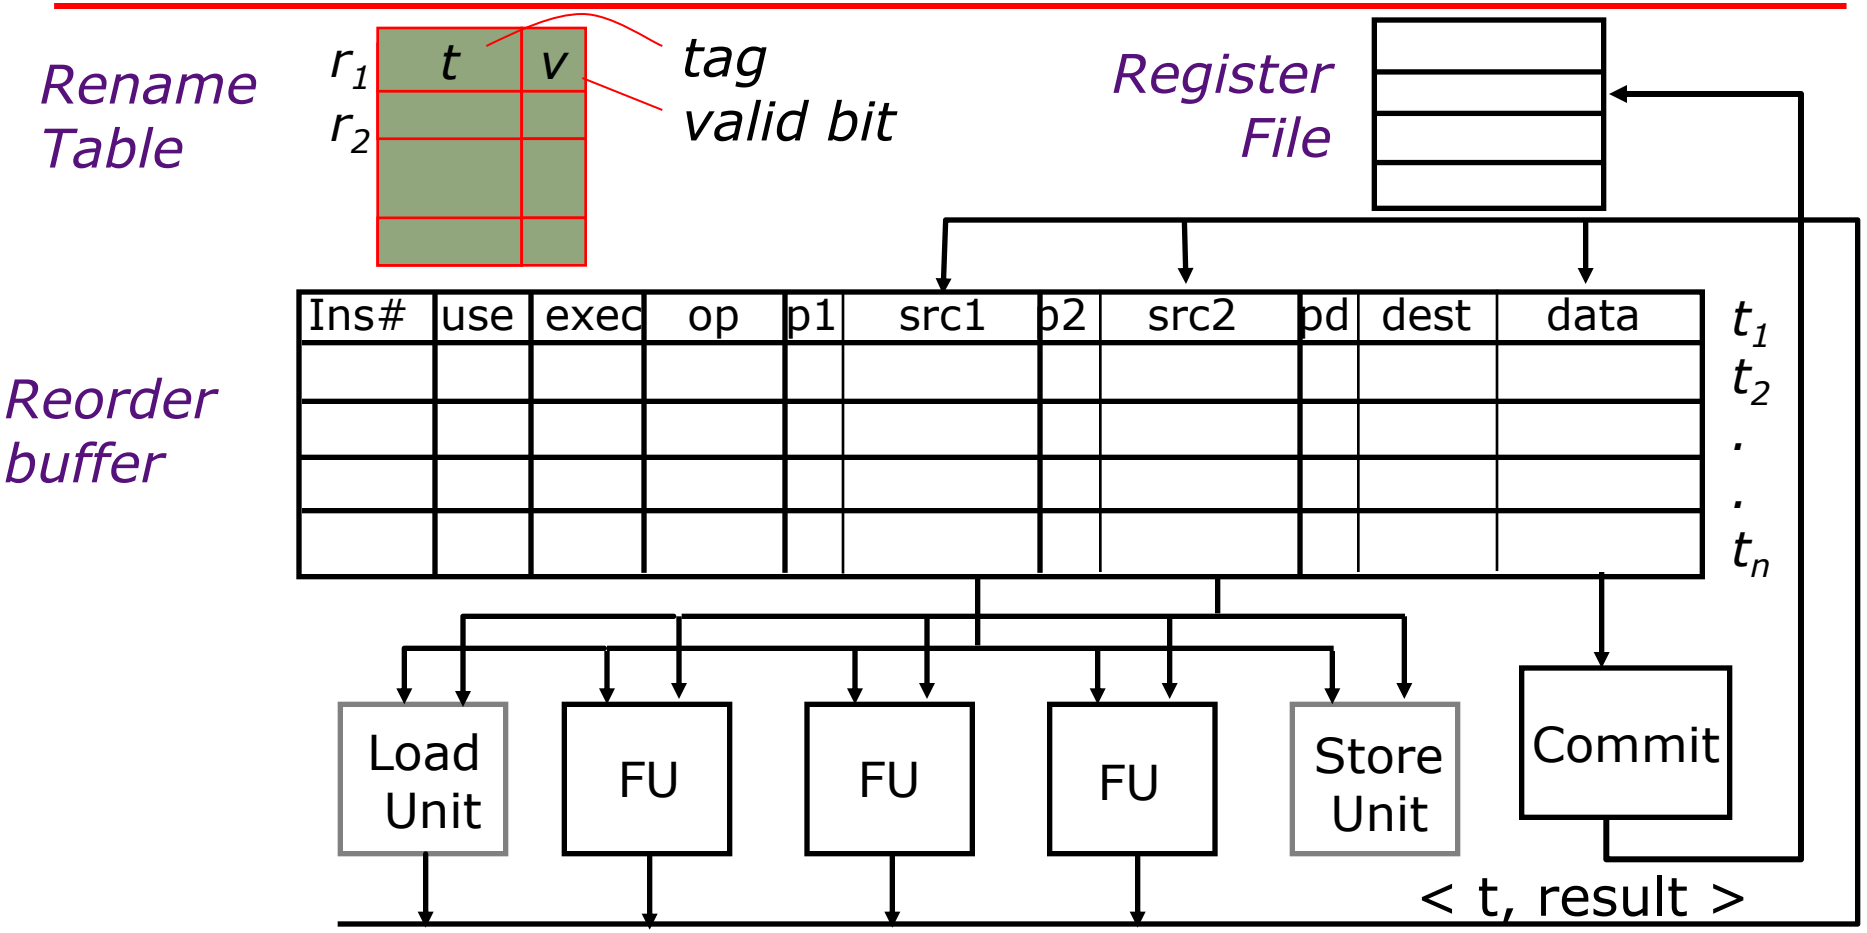


Register file does not contain renaming tags any more.

How does the decode stage find the tag of a source register?

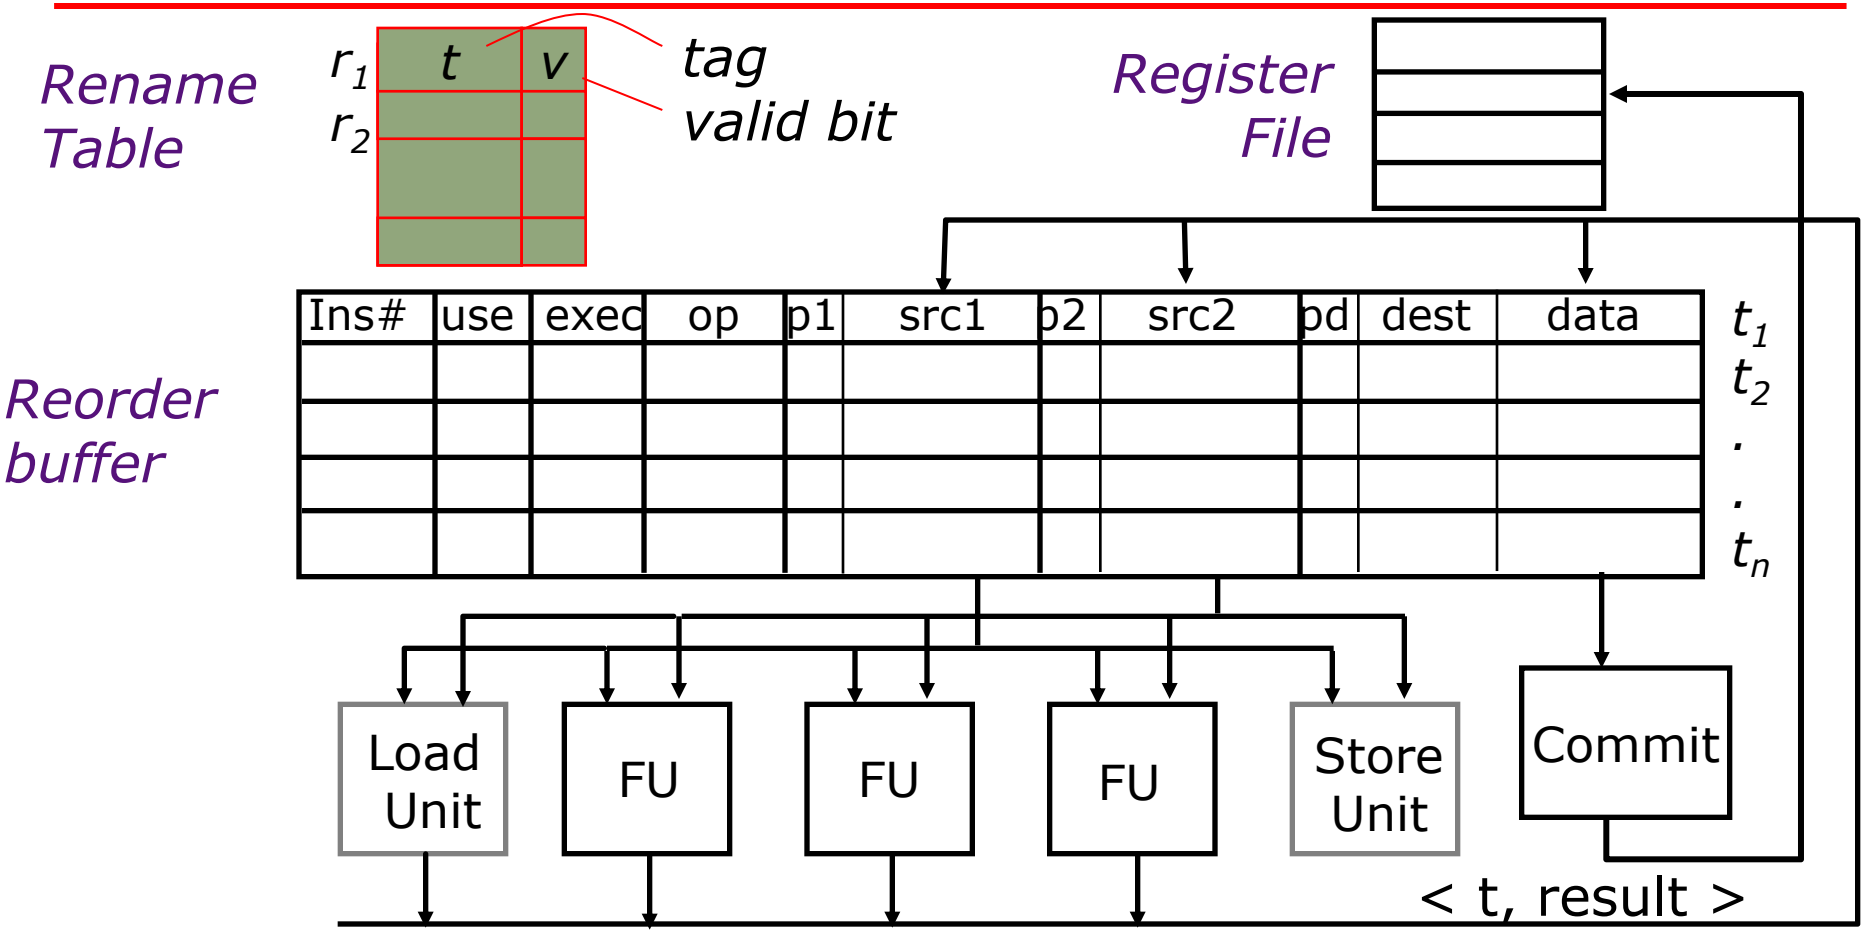
Search the "dest" field in the reorder buffer

Renaming Table



Renaming table is a cache to speed up register name lookup.
It needs to be cleared after each exception taken.
When else are valid bits cleared?

Renaming Table



Renaming table is a cache to speed up register name lookup.
It needs to be cleared after each exception taken.
When else are valid bits cleared? *Control transfers*

Physical Register Files

- Reorder buffers are space inefficient – a data value may be stored in multiple places in the reorder buffer
- idea – keep all data values in a physical register file
  - Tag represents the name of the data value and name of the physical register that holds it
  - Reorder buffer contains only tags

Thus, 64 data values may be replaced by 8-bit tags for a 256 element physical register file

More on this in later lectures …

Branch Penalty

Next fetch started

How many instructions need to be killed on a misprediction?

Modern processors may have > 10 pipeline stages between nextPC calculation and branch resolution !
