The Shift to Multicore

- Since 2005, improvements in system performance mainly due to increasing cores/chip
- Why? Limited instruction-level parallelism
  Technology scaling
Multicore Performance

Cost/perf curve of possible core designs

- High-perf, expensive core
- Moderate perf, efficient core

What factors may limit multicore performance?

- Limited application parallelism
- Memory accesses and inter-core communication
- Programming complexity

Amdahl’s Law

- Speedup = \( \frac{\text{time}_{\text{without enhancement}}}{\text{time}_{\text{with enhancement}}} \)
- Suppose an enhancement speeds up a fraction \( f \) of a task by a factor of \( S \)
  \[
  \text{time}_{\text{new}} = \text{time}_{\text{old}} \cdot \left( (1-f) + \frac{f}{S} \right) \\
  S_{\text{overall}} = \frac{1}{(1-f) + \frac{f}{S}}
  \]

Corollary: Make the common case fast
Amdahl’s Law and Parallelism

- Say you write a program that can do 90% of the work in parallel, but the other 10% is sequential.
- What is the maximum speedup you can get by running on a multicore machine?

\[
S_{\text{overall}} = \frac{1}{(1-f) + \frac{f}{S}}
\]

\[
f = 0.9, \ S=\infty \rightarrow S_{\text{overall}} = 10
\]

What \(f\) do you need to use a 1000-core machine well?
Communication Models

• **Shared memory:**
  - Single address space
  - Implicit communication by reading/writing memory
    • Data
    • Control (semaphores, locks, barriers, ...)
  - Low-level programming model: threads

• **Message passing:**
  - Separate address spaces
  - Explicit communication by send/rcv messages
    • Data & control (blocking msgs, barriers, ...)
  - Low-level programming model: processes + inter-process communication (e.g., MPI)

• Pros/cons of each model?
Coherence & Consistency

- Shared memory systems:
  - Have multiple private caches for performance reasons
  - Need to provide the illusion of a single shared memory

- Intuition: A read should return the most recently written value
  - What is “most recent”?

- Formally:
  - Coherence: What values can a read return?
    - Concerns reads/writes to a single memory location
  - Consistency: When do writes become visible to reads?
    - Concerns reads/writes to multiple memory locations
Cache Coherence Avoids Stale Data

- A cache coherence protocol controls cache contents to avoid stale cache lines
Implementing Cache Coherence

- Coherence protocols must enforce two rules:
  - Write propagation: Writes eventually become visible to all processors
  - Write serialization: Writes to the same location are serialized (all processors see them in the same order)

- How to ensure write propagation?
  - Write-invalidate protocols: Invalidate all other cached copies before performing the write
  - Write-update protocols: Update all other cached copies after performing the write

- How to track sharing state of cached data and serialize requests to the same address?
  - Snooping-based protocols: All caches observe each other’s actions through a shared bus
  - Directory-based protocols: A coherence directory tracks contents of private caches and serializes requests
Snooping-Based Coherence [Goodman 1983]

Caches watch (snoop on) bus to keep all processors’ view of memory coherent.
Snooping-Based Coherence

- Bus provides serialization point
  - Broadcast, totally *ordered*
  - Each cache controller “snoops” all bus transactions
  - Controller updates state of cache in response to processor and snoop events and generates bus transactions

- Snoopy protocol (FSM)

Cache interventions

- MSI allows caches to serve writes without updating memory, so main memory can have stale data
  - Core 0’s cache needs to supply data
  - But main memory may also respond!

- Cache must override response from main memory

MSI Optimizations: Exclusive State

• Observation: Doing read-modify-write sequences on private data is common
  – What’s the problem with MSI?

• Solution: E state (exclusive, clean)
  – If no other sharers, a read acquires line in E instead of S
  – Writes silently cause E→M (exclusive, dirty)
MESI: An Enhanced MSI protocol
increased performance for private read-write data

Each cache line has a tag

Address tag

M: Modified Exclusive
E: Exclusive, unmodified
S: Shared
I: Invalid

MSI Optimizations: Owner State

- **Observation:** On M→S transitions, must write back line!
  - What happens with frequent read-write sharing?
  - Can we defer the write after S?

- **Solution:** O state (Owner)
  - O = S + responsibility to write back
  - On M→S transition, one sharer (typically the one who had the line in M) retains the line in O instead of S
  - On eviction, O writes back line (or another sharer does S→O)

- **MSI, MESI, MOSI, MOESI...**
  - Typically E if private read-write >> shared read-only (common)
  - Typically O only if writebacks are expensive (main mem vs L3)
Split-Transaction and Pipelined Buses

Atomic Transaction Bus

- Supports multiple simultaneous transactions
  - Higher throughput
  - Responses may arrive out of order
- Often implemented as multiple buses (req+resp)

Split-Transaction Bus

Simple, but low throughput!
Non-Atomicity → Transient States

- Protocol must handle lack of atomicity
- Two types of states
  - Stable (e.g. MSI)
  - Transient
- Split + race transitions
- Higher complexity

Scaling Cache Coherence

- Can implement ordered interconnects that scale better than buses...

Starfire E10000 (drawn with only eight processors for clarity). A coherence request is unicast up to the root, where it is serialized, before being broadcast down to all processors.

- ... but broadcast is fundamentally unscalable
  - Bandwidth, energy of transactions with 100s of cache snoops?
Directory-Based Coherence

- Route all coherence transactions through a directory
  - Tracks contents of private caches \(\rightarrow\) No broadcasts
  - Serves as ordering point for conflicting requests \(\rightarrow\) Unordered networks

(more on next lecture)
A cache block contains more than one word and cache coherence is done at the block-level and not word-level.

Suppose $P_1$ writes word$_i$ and $P_2$ writes word$_k$ and both words have the same block address.

*What can happen?* The block may be invalidated (ping-pong) many times unnecessarily because addresses are in the same block.
Cache coherence protocols will cause `mutex` to ping-pong between P1’s and P2’s caches.

Ping-ponging can be reduced by first reading the `mutex` location (*non-atomically*) and executing a swap only if it is found to be zero (test&test&set).
CC and Bus Occupancy
Performance Issue - 3

In general, an atomic *read-modify-write* instruction requires two memory (bus) operations without intervening memory operations by other processors.

In a multiprocessor setting, bus needs to be locked for the entire duration of the atomic read and write operation

⇒ expensive for simple buses
⇒ *very expensive* for split-transaction buses

modern processors use

*load-reserve*
*store-conditional*
Load-reserve & Store-conditional

Special register(s) to hold reservation flag and address, and the outcome of store-conditional

<table>
<thead>
<tr>
<th>Load-reserve R, (a):</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;flag, adr&gt; ← &lt;1, a&gt;;</td>
</tr>
<tr>
<td>R ← M[a];</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Store-conditional (a), R:</th>
</tr>
</thead>
<tbody>
<tr>
<td>if &lt;flag, adr&gt; == &lt;1, a&gt;</td>
</tr>
<tr>
<td>then cancel other procs’ reservation on a;</td>
</tr>
<tr>
<td>M[a] ← &lt;R&gt;;</td>
</tr>
<tr>
<td>status ← succeed;</td>
</tr>
<tr>
<td>else status ← fail;</td>
</tr>
</tbody>
</table>

If the snooper sees a store transaction to the address in the reserve register, the reserve bit is set to 0
- Several processors may reserve ‘a’ simultaneously
- These instructions are like ordinary loads and stores with respect to the bus traffic
Performance: 
Load-reserve & Store-conditional

The total number of memory (bus) transactions is not necessarily reduced, but splitting an atomic instruction into load-reserve & store-conditional:

- *increases bus utilization* (and reduces processor stall time), especially in split-transaction buses

- *reduces cache ping-pong effect* because processors trying to acquire a mutex do not have to perform stores each time
