## Problem M3.2: Branch Prediction [? Hours]

Problem M3.2.A
Program
R2 contains the number of non-zero entries in the first $n$ elements of array.

## Problem M3.2.B

2-bit branch prediction
There are 7 mispredicts (shown in bold italics).

Table M3.2-3

The first thing to notice is that the more history bits we have, the longer it takes to get any correct prediction since we have to "train" the predictor. These start-up costs go up as the number of history bits increase.

Another thing to notice is that the single history bit does not help at all (even after we get into a steady-state phase). In both the single history bit and no history cases, the b2 branch is predicted correctly once we get past the start-up phase (since b2 is always taken). The single bit of history does not help since this history is too "nearsighted". The second history bit captures the alternating pattern of the bl branch, and hence does not mispredict once it gets past the start-up phase. For a large n then, the 2-bit history predictor is the best.

The final point of observation is that all the predictors mispredict the fall-through case (the last b2 branch).

Analysis II

When the input is random, no prediction scheme will help predict whether b1 is taken or not. All three schemes will eventually predict b2 as always taken. However, the more history bits are used, the more sets need to be trained to predict the always taken for b 2 . Thus, the more history bits used, the more mispredicts of branch b2 will occur initially. The answer does not depend on the size of n . However, as n gets large, the start-up costs become insignificant among the three schemes.

The moral of the problem is that history bits are useful if there is a pattern among a sequence of branches. The longer this pattern is, the more history bits are needed to be able to recognize this pattern. If the pattern is not recognized, then global history bits can hurt because it take longer to train the branches that can be predicted correctly.
