# Graphics Processing Units (GPUs)

Joel Emer
Computer Science & Artificial Intelligence Lab
M.I.T.

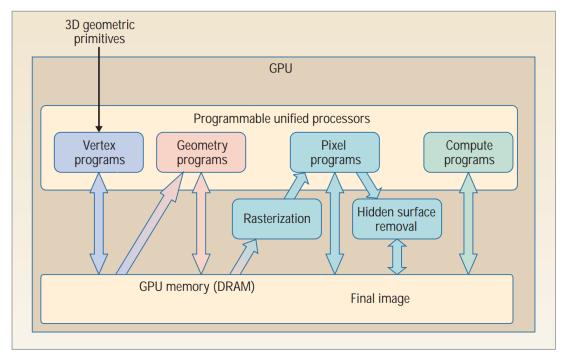

### Why Study GPUs?

- Very successful commodity accelerator/co-processor
- GPUs combine two strategies to increase efficiency
  - Massive parallelism
  - Specialization
- Illustrates tension between performance and programmability in accelerators

### **Graphics Processors Timeline**

- Until mid-90s
  - Most graphics processing in CPU
  - VGA controllers used to accelerate some display functions
- Mid-90s to mid-2000s
  - Fixed-function accelerators for 2D and 3D graphics
    - triangle setup & rasterization, texture mapping & shading
  - Programming:
    - OpenGL and DirectX APIs

### Contemporary GPUs

Luebke and Humphreys, 2007

#### Modern GPUs

- Some fixed-function hardware (texture, raster ops, ...)
- Plus programmable data-parallel multiprocessors
- Programming:
  - OpenGL/DirectX
  - Plus more general purpose languages (CUDA, OpenCL, ...)

### GPUs in Modern Systems

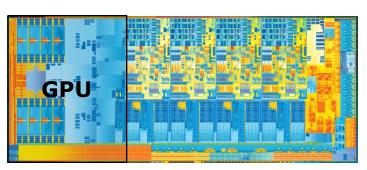

#### Discrete GPUs

- PCIe-based accelerator
- Separate GPU memory

- CPU and GPU on same die
- Shared main memory and last-level cache

Pros/cons?

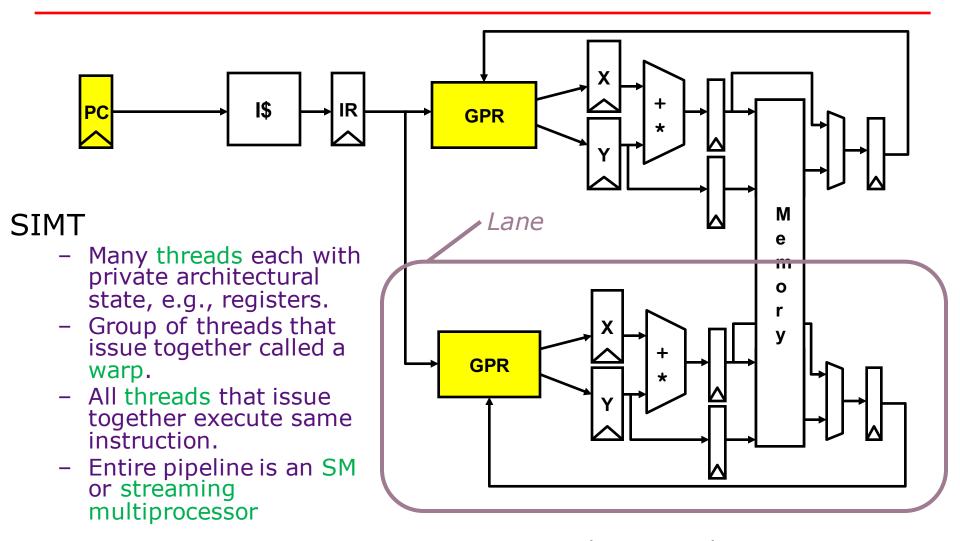

Intel Ivy Bridge, 22nm 160mm<sup>2</sup>

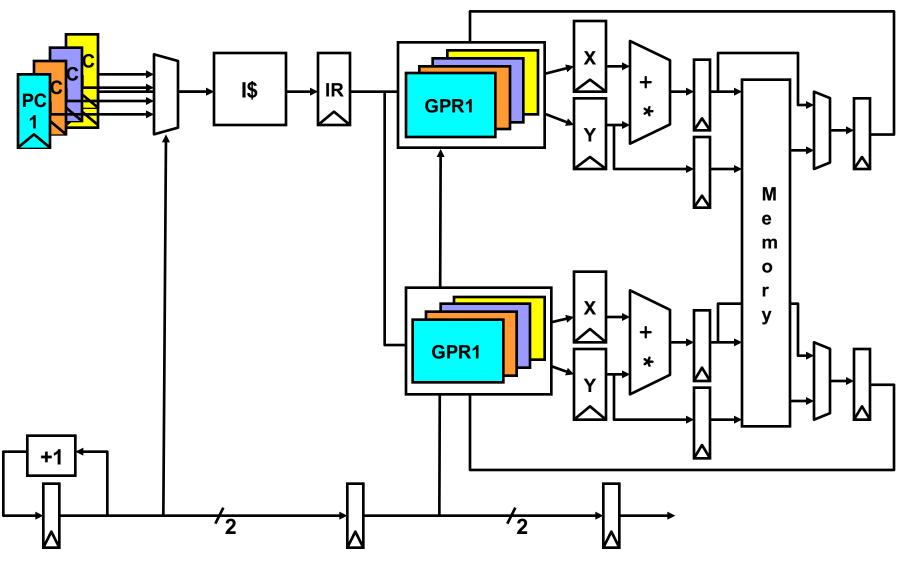

Apple A7, 28nm TSMC, 102mm<sup>2</sup>

# Single Instruction Multiple Thread

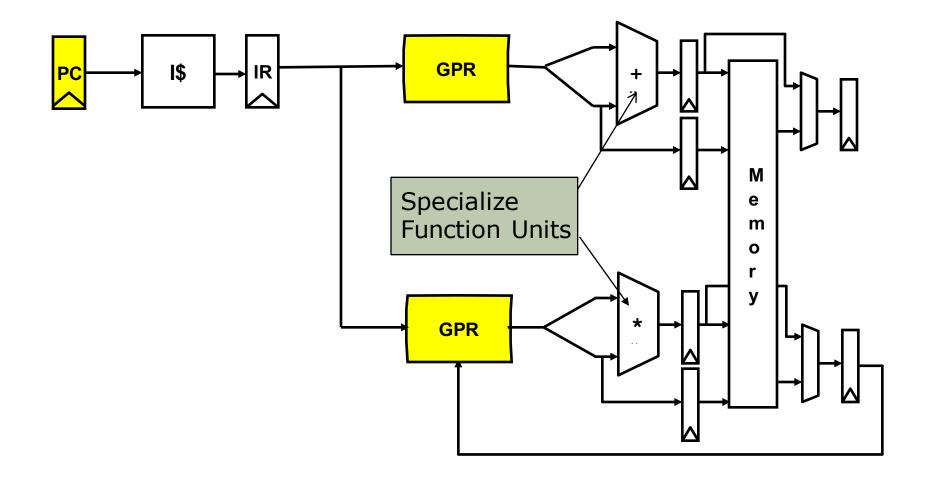

green-> Nvidia terminology

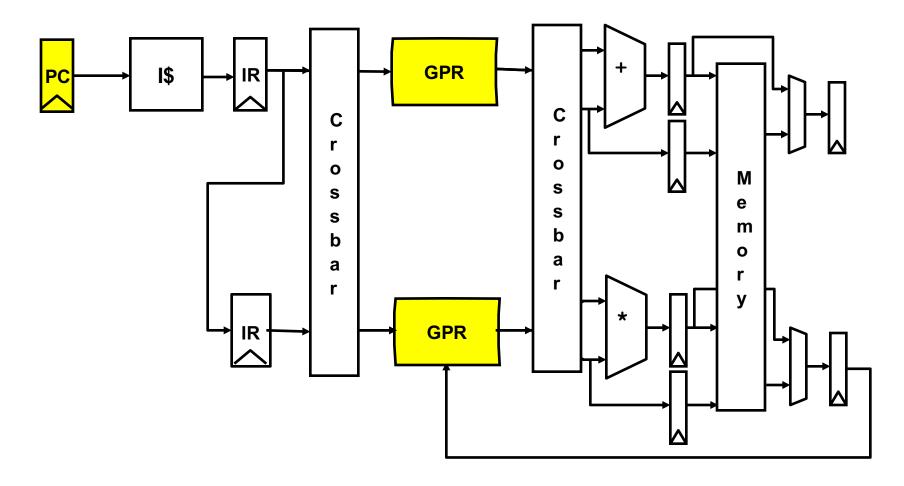

### Multiple Thread – Single Instruction Multiple Thread

## Function unit optimization

### Function unit optimization

Restriction: Can't issue same operation twice in a row

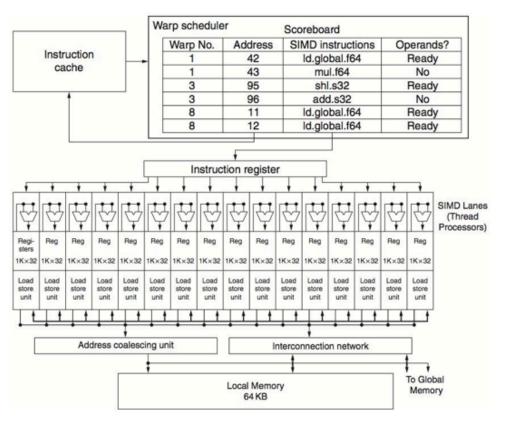

### Function unit optimization

### Cycle

|                  |       | 0                    | 1                    | 2           | 3                    | 4                  | 5   |

Key Opcode<sub>inum,thread(s)</sub>

## Streaming Multiprocessor Overview

- Each SM supports 10s of warps (e.g., 64 in Kepler) with 32 threads/warp
- Fetch 1 instr/cycle
- Issue 1 ready instr/cycle
  - Simple scoreboarding: all warp elements must be ready
- Instruction broadcast to all lanes
- Multithreading is the main latency-hiding mechanism

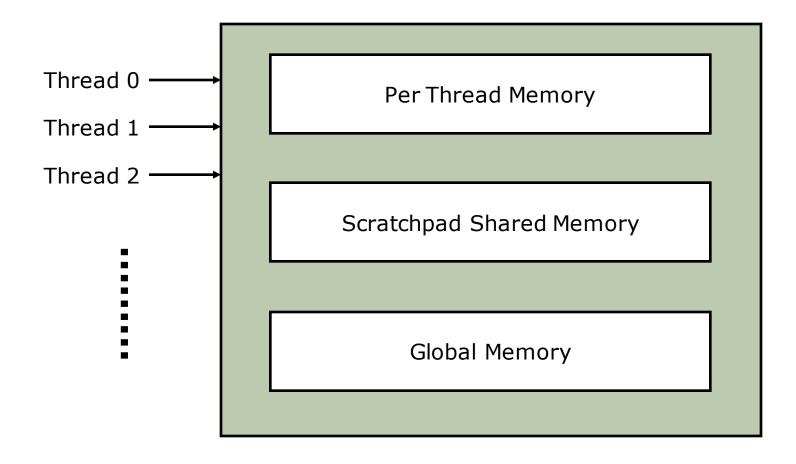

What average latency is needed to keep busy?

64

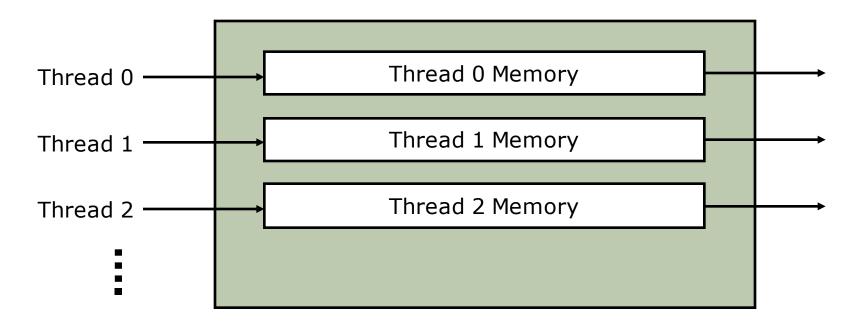

### Context Size vs Number of Contexts

- SMs support a variable number of contexts based on required registers (and shared memory)
  - Few large contexts → Fewer register spills
  - Many small contexts → More latency tolerance
  - Choice left to the compiler
- Example: Kepler supports up to 64 warps
  - Max: 64 warps @ <=32 registers/thread</p>
  - Min: 8 warps @ 256 registers/thread

# Many Memory Types

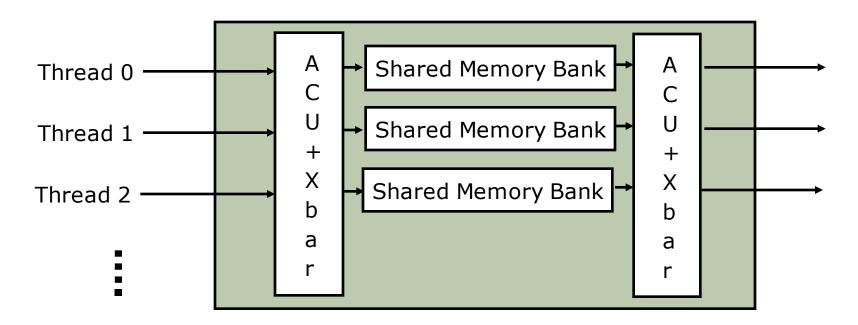

## Private Per Thread Memory

#### Private memory

- No cross-thread sharing
- Small, fixed size memory
  - Can be used for constants
- Multi-bank implementation (can be in global memory)

# Shared Scratchpad Memory

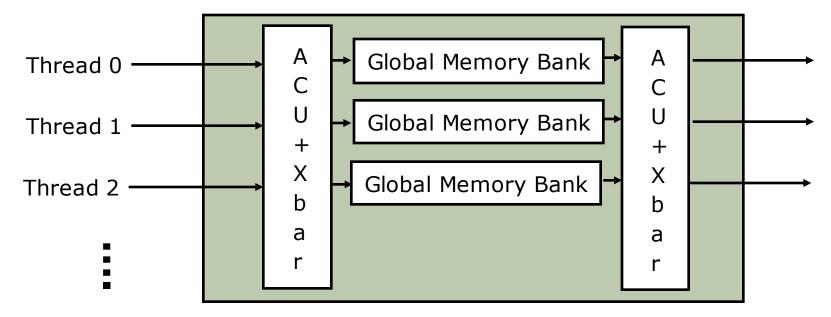

- Shared scratchpad memory (threads share data)
  - Small, fixed size memory (16K-64K / 'core')
  - Banked for high bandwidth
  - Fed with address coalescing unit +crossbar
    - ACU can buffer/coalesce requests

## Memory Access Divergence

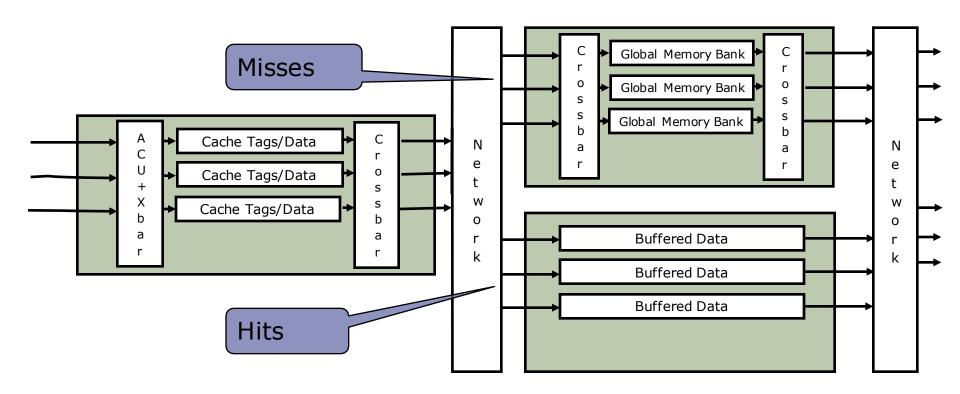

- All loads are gathers, all stores are scatters
- Address coalescing unit detects sequential and strided patterns, coalesces memory requests, but complex patterns can result in multiple lower bandwidth requests (memory divergence)
- Writing efficient GPU code requires most accesses to not conflict, even though programming model allows arbitrary patterns!

# Shared Global Memory

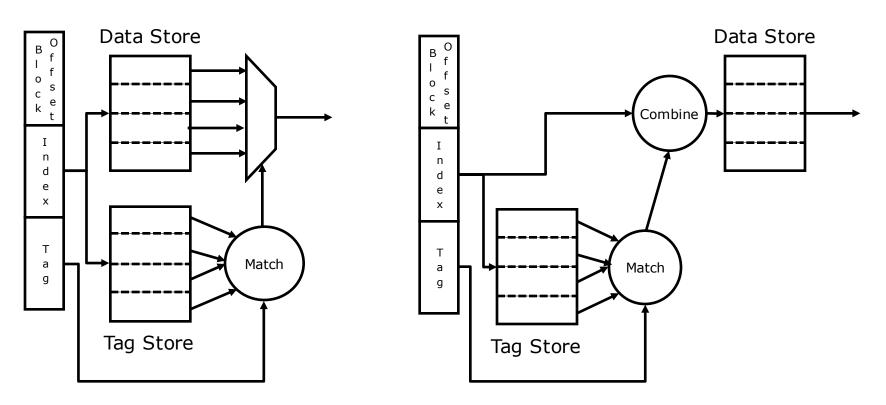

- Shared global memory
  - Large shared memory
  - Will suffer also from memory divergence

## Shared Global Memory

- Memory hierarchy with caches
  - Cache to save memory bandwidth
  - Caches also enable compression/decompression of data

### Serialized cache access

- Trade latency for power/flexibility
  - Only access data bank that contains data
  - Facilitate more sophisticated cache organizations
    - e.g., greater associatively

## Handling Branch Divergence

- Similar to vector processors, but masks are handled internally
  - Per-warp stack stores PCs and masks of non-taken paths
- On a conditional branch
  - Push the current mask onto the stack
  - Push the mask and PC for the non-taken path
  - Set the mask for the taken path
- At the end of the taken path
  - Pop mask and PC for the non-taken path and execute
- At the end of the non-taken path
  - Pop the original mask before the branch instruction
- If a mask is all zeros, skip the block

# Example: Branch Divergence

```
Assume 4 threads/warp,
initial mask 1111
if (m[i] != 0) {
  if (a[i] > b[i]) {
    y[i] = a[i] - b[i];
  } else {
    y[i] = b[i] - a[i];
} else {
 y[i] = 0;
```

- Push mask 1111
  Push mask 0011
  Set mask 1100
- Push mask 1100 Push mask 0100 Set mask 1000
- 3 Pop mask 0100
- Pop mask 1100 Pop mask 0011

Pop mask 1111

Optimization for branches that all go same way?

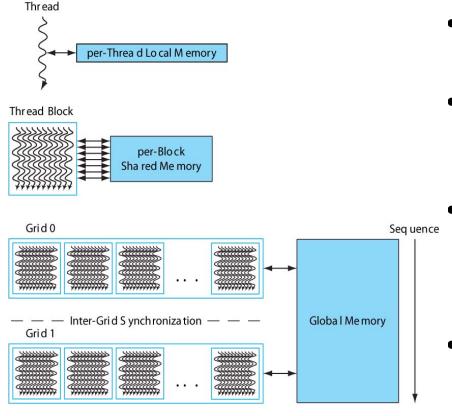

# Branch divergence and locking

 Consider the following executing in multiple threads in a warp:

```
if (condition[i]) {
  while (locked(map0[i]])){}
  lock(locks[map0[i]]);
} else {
  unlock(locks[map1[i]);
}
```

```
where i is a thread id and
map0[], map1[] are permutations of thread ids.
```

### CUDA GPU Thread Model

- Single-program multiple data (SPMD) model
- Each context is a thread
  - Threads have registers
  - Threads have local memory
- Parallel threads packed in blocks
  - Blocks have shared memory
  - Threads synchronize with barrier
  - Blocks run to completion (or abort)
- Grids include independent blocks
  - May execute concurrently
  - Share global memory, but
  - Have limited inter-block synchronization

### Code Example: DAXPY

#### C Code

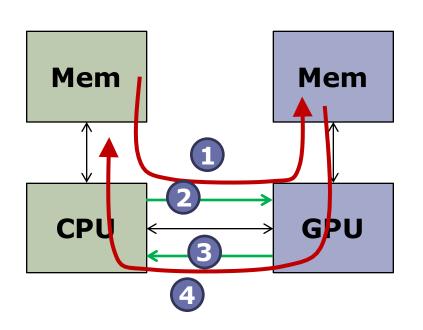

```
// Invoke DAXPY  \begin{aligned} &\text{daxpy}(n, 2.0, x, y); \\ &\text{// DAXPY in C} \\ &\text{void daxpy}(int \ n, \ double \ a, \ double \ *x, \ double \ *y)} \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & & \\ & & & \\ & & & & \\ & & & \\ & & & & \\ & & & \\ & & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & & & \\ & &
```

#### **CUDA Code**

```
// Invoke DAXPY with 256 threads per block
__host__
int nblocks = (n+ 255) / 256;
    daxpy<<<nblocks, 256>>>(n, 2.0, x, y);
// DAXPY in CUDA
__device__
void daxpy(int n, double a, double *x, double *y)
{
    int i = blockIdx.x*blockDim.x + threadIdx.x;
    if (i < n) y[i] = a*x[i] + y[i];
}</pre>
```

- CUDA code launches 256 threads per block
- CUDA vs vector terminology:
  - Thread = 1 iteration of scalar loop (1 element in vector loop)
  - Block = Body of vectorized loop (VL=256 in this example)
  - Grid = Vectorizable loop

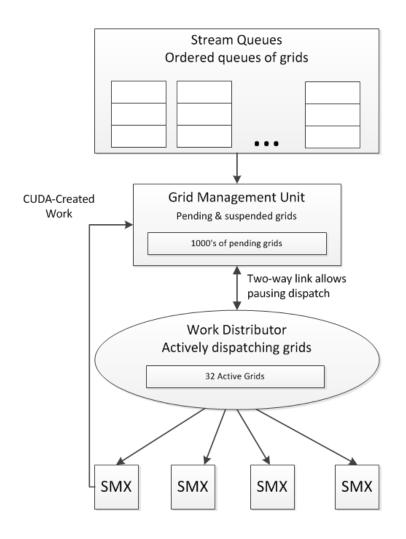

### **GPU Kernel Execution**

- Transfer input data from CPU to GPU memory
- 2 Launch kernel (grid)
- Wait for kernel to finish (if synchronous)
- Transfer results to CPU memory

- Data transfers can dominate execution time
- Integrated GPUs with unified address space
   → no copies, but...

# Hardware Scheduling

- Grids can be launched by CPU or GPU
  - Work from multiple CPU threads and processes
- HW unit schedules grids on SMX
  - Priority-based scheduling
- 32 active grids
  - More queued/paused

## Synchronization

- Barrier synchronization within a thread block (\_\_syncthreads())
  - Tracking simplified by grouping threads into warps
  - Counter tracks number of warps that have arrived to barrier
- Atomic operations to global memory
  - Read-modify-write operations (add, exchange, compare-andswap, ...)
  - Performed at the memory controller or at the L2
- Limited inter-block synchronization!
  - Can't wait for other blocks to finish

### **GPU ISA and Compilation**

 GPU microarchitecture and instruction set change very frequently

- To achieve compatibility:
  - Compiler produces intermediate pseudo-assembler language (e.g., Nvidia PTX)
  - GPU driver JITs kernel, tailoring it to specific microarchitecture

- In practice, little performance portability
  - Code is often tuned to specific GPU architecture

### System-Level Issues

#### Instruction semantics

Exceptions

#### Scheduling

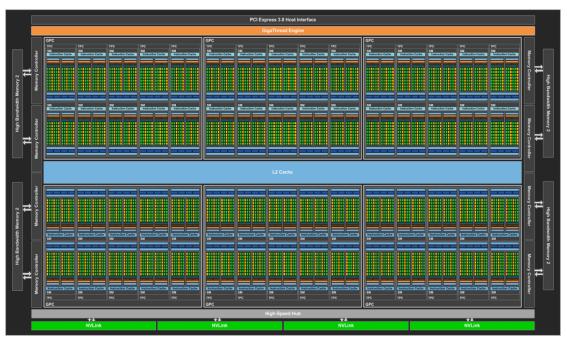

- Each kernel is non-preemptive (but can be aborted)
- Resource management and scheduling left to GPU driver, opaque to OS

### Memory management

- First GPUs had no virtual memory
- Recent support for basic virtual memory (protection among grids, no paging)
- Host-to-device copies with separate memories (discrete GPUs)

### GPU: Multithreaded Multicore Chip

• Example: Nvidia Pascal GP100 (2016)

- 60 streaming multiprocessor clusters (SMM)
- 4MB Shared L2 cache
- 8 memory controllers
  - 720 GB/s (HBM2)
- Fixed-function logic for graphics (texture units, raster ops, ...)
- Scalability → change number of cores and memory channels
- Scheduling mostly controlled by hardware

### Pascal Streaming Multiprocessor (SMM)

#### Execution units

- 64 FUs (int and FP)
- 16 load-store FUs
- 16 specialFUs (e.g., sqrt, sin, cos, ...)

### Memory structures

- 64K 32-bit registers
- 64KB shared memory

#### Contexts

- 2048 threads
- 32 blocks

# Vector vs GPU Terminology

| Туре                 | More descrip-<br>tive name             | Closest old term<br>outside of GPUs           | Official CUDA/<br>NVIDIA GPU term | Book definition   |

Next: Transactions
Thank you!

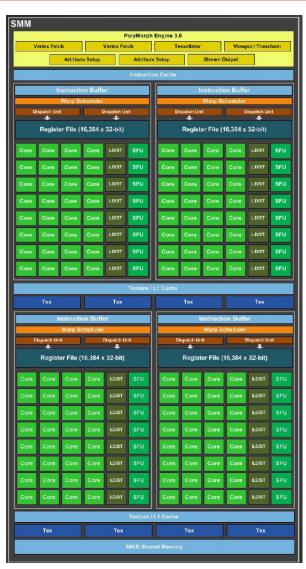

### GPU: Multithreaded Multicore Chip

• Example: Nvidia Maxwell GM204

- 16 streaming multiprocessor clusters (SMM)
- 2MB Shared L2 cache
- 4 memory controllers
  - 244 GB/s
- Fixed-function logic for graphics (texture units, raster ops, ...)
- Scalability > change number of cores and memory channels
- Scheduling mostly controlled by hardware

### Maxwell Streaming Multiprocessor (SMM)

#### Execution units

- 128 FUs (int and FP)
- 32 load-store FUs
- 32 special-function FUs (e.g., sqrt, sin, cos, ...)

### Memory structures

- 64K 32-bit registers
- 96KB shared memory
