

## Problem M10.1: Multithreading

### Problem 10.1.A

---

Since there is no penalty for conditional branches, instructions take one cycle to execute unless there is a dependency problem. The following table summarizes the execution time for each instruction. From the table, the loop takes **104 cycles** to execute.

Instruction	Start Cycle	End Cycle
LW R3, 0(R1)	1	100
LW R4, 4(R1)	2	101
SEQ R3, R3, R2	101	101
BNEZ R3, End	102	102
ADD R1, R0, R4	103	103
BNEZ R1, Loop	104	104

### Problem M10.1.B

---

If we have  $N$  threads and the first load executes in cycle 1, SEQ, which depends on the load, executes in cycle  $2N + 1$ . To fully utilize the processor, we need to hide the 100-cycle memory latency,  $2N + 1 \geq 101$ . The minimum number of thread needed is **50**.

### Problem M10.1.C

---

	Throughput	Latency
<b>Better</b>	✓	
<b>Same</b>		
<b>Worse</b>		✓

### Problem M10.1.D

---

In steady state, each thread can execute 6 instructions (SEQ, BNEZ, ADD, BNEZ, LW, LW). Therefore, to hide 99 cycles between the second LW and SEQ, a processor needs  $\lceil 99/6 \rceil + 1 = 18$  threads.

## **Problem M10.2: Multithreaded architectures**

### **Problem M10.2.A**

---

4, since the largest latency for any instruction is 4.

### **Problem M10.2.B**

---

$2/12 = 0.17$  flops/cycle, on average we complete a loop every 12 cycles

### **Problem M10.2.C**

---

Yes, we can hide the latency of the floating point instructions by moving the add instructions in between floating point and store instructions – we'd only need 3 threads. Moving the third load up to follow the second load would further reduce thread requirement to only 2.

## **Problem M10.3: Multithreading**

### **Problem M10.3.A**

---

**Fixed Switching:**         6         Thread(s)

If we have  $N$  threads and L.D. executes in cycle 1, FADD, which depends on the load executes in cycle  $2N + 1$ . To fully utilize the processor, we need to hide 12-cycle memory latency,  $2N + 1$  13. The minimum number of thread needed is 6.

**Data-dependent Switching:**         4         Thread(s)

In steady state, each thread can execute 4 instructions (FADD, BNE, LD, ADDI). Therefore, to hide 11 cycles between ADDI and FADD, a processor needs  $11/4 + 1 = 4$  threads.

### **Problem M10.3.B**

---

**Fixed Switching:**         2         Thread(s)

Each FADD depends on the previous iteration's FADD. If we have  $N$  threads and the first FADD executes in cycle 1, the second FADD executes in cycle  $4N + 1$ . To fully utilize the processor, we need to hide 5-cycle latency,  $4N + 1$  6. The minimum number of thread needed is 2.

**Data-dependent Switching:**         2         Thread(s)

In steady state, each thread can execute 4 instructions (FADD, BNE, LD, ADDI). Therefore, to hide 2 cycles between ADDI and FADD, a processor needs  $2/4 + 1 = 2$  threads.

**Problem M10.3.C**

---

Consider a **Simultaneous Multithreading (SMT)** machine with limited hardware resources. **Circle** the following hardware constraints that can limit the total number of threads that the machine can support. For the item(s) that you circle, **briefly describe** the minimum requirement to support  $N$  threads.

- (A) Number of Functional Units      Since not all the threads are executed in each cycle, the number of functional unit is not a constraint that limits the total number of threads that the machine can support.
- (B) Number of Physical Registers      We need at least  $[N \text{ (number of architecture registers)} + 1]$  physical registers.
- (C) Data Cache Size      This is for performance reasons.
- (D) Data Cache Associativity      This is for performance reasons.

## **Problem M10.4: Multithreading (Spring 2015 Quiz 2, Part D)**

Consider the following instruction sequence.

```
        addi    r3, r0, 256
loop:   lw      f1, r1, #0
        lw      f2, r2, #0
        mul     f3, f1, f2
        sw      f3, r2, #0
        addi    r1, r1, #4
        addi    r2, r2, #4
        addi    r3, r3, #-1
        bnez   r3, loop
```

Assume that memory operations take 4 cycles (i.e., if instruction I1 starts execution at cycle N, then instructions that depend on the result of I1 can only start execution at or after cycle N+4); multiply instructions take 6 cycles; and all other operations take 1 cycle. Assume the multiplier and memory are pipelined (i.e., they can start a new request every cycle). Also assume perfect branch prediction.

### **Problem M10.4.A**

---

Suppose the processor performs fine-grained multithreading with fixed round-robin switching: the processor switches to the next thread every cycle, and if the instruction of the next thread is not ready, it inserts a bubble into the pipeline. What is the minimum number of threads required to fully utilize the processor every cycle while running this code?

6 threads to cover the latency between mul and sw

### **Problem M10.4.B**

---

Suppose the processor performs coarse-grained multithreading, i.e. the processor only switches to another thread when there is a L2 cache miss. Will the following three metrics increase or decrease, compared to fixed round-robin switching? Use a couple of sentences to answer the following questions.

1) Compared to fixed round-robin switching, will the **number of threads needed for the highest achievable utilization** increase or decrease? Why?

It will decrease because the processor will switch less frequently and stall for instructions with long latency (e.g. mul).

2) Compared to fixed round-robin switching, will the **highest achievable pipeline utilization** increase or decrease? Why?

It will decrease because the processor will stall for instructions with long latency (e.g. mul) and insert bubbles into pipeline.

3) Compared to fixed round-robin switching, will **cache hit rate** increase or decrease? Why?

It will increase since there will be less threads competing the cache capacity.
