L08-1

Higher-order List abstractions

```
map f []          = []
map f (x:xs)      = (f x):(map f xs)      ?
map :: (tx -> ty) -> (List tx) -> (List ty)

foldl f z []      = z
foldl f z (x:xs)  = foldl f (f z x) xs      ?
foldl :: (tz -> tx -> tz) -> tz -> (List tx) -> tz

foldr f z []      = z
foldr f z (x:xs)  = f x (foldr f z xs)      ?
foldr :: (tx -> tz -> tz) -> tz -> (List tx) -> tz

filter p []       = []
filter p (x:xs)   = if p x
                    then x:(filter p xs)
                    else filter p xs      ?
```

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-2

Using maps and folds

1. Write `sum` in terms of `fold`

```
sum = foldr plus 0
```

2. Write `split` using `foldr`

```
split :: (List Token) -> ((List String),(List Int))
```

```
split = foldr f ([],[])
```

```
f (Word w) (ws,ns) = ((w:ws),ns)
```

```
f (Number n) (ws,ns) = (ws,(n:ns))
```

3. What does function `fy` do?

```
fy xys = map second xys
```

```
second (x,y) = y
```

```
fy :: (List (t1, t2)) -> (List t2)
```

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-3

Flattening a List of Lists

```
append :: (List t) -> (List t) -> (List t)
```

```
append [] ys = ys
```

```
append (x:xs) ys = (x:(append xs ys))
```

```
flatten :: (List (List t)) -> (List t)
```

```
flatten [] = []
```

```
flatten (xs:xss) = append xs (flatten xss)
```

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-4

Zippping two lists

```
zipWith :: (tx -> ty -> tz) ->
          (List tx) ->
          (List ty) -> (List tz)
```

```
zipWith f [] [] = []
zipWith f (x:xs) (y:ys) =
```

```
    ((f x y):(zipWith f xs ys))
```

?

What does `f` do?

```
f xs = zipWith append xs (init ([]:xs))
```

Suppose `xs` is:

```
x0 , x1 , x2 , ... , xn
```

```
[] , x0 , x1 , ... , xn-1
```

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-5

Arithmetic Sequences: Special Lists

```
[1 .. 4] ≡ [1,2,3,4]
```

```
[1,3 .. 10] ≡ [1,3,5,7,9]
```

```
[5,4 .. 1] ≡ [5,4,3,2,1]
```

```
[5,5 .. 10] ≡ [5,5,5,...]
```

?

```
[5 .. ] ≡ [5,6,7,...]
```

?

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-6

Infinite Data Structures

1. `ints_from i = i:(ints_from (i+1))`
`nth n (x:xs) = if n == 1 then x`
`else nth (n - 1) xs`
`nth 50 (ints_from 1) --> 50 ?`
2. `ones = 1:ones`
`nth 50 ones --> 1 ?`
3. `xs = map f (a:xs)`
`nth 10 xs --> f(f...(f a)...) ?`

These are well defined programs in Haskell. In pH you will get an answer but the program may *not* terminate.

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-7

Primes: *The Sieve of Eratosthenes*

```
primes = sieve [2..]
sieve (x:xs) = x:(sieve (filter (p x) xs))
p x y = (y mod x) ≠ 0

nth 100 primes
```

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-8

List Comprehensions

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-9

List Comprehensions

a convenient syntax

```
[ e | gen, gen, ... ]
```

Examples

```
[ f x | x <- xs ]  
means map f xs
```

```
[ x | x <- xs, (p x) ]  
means filter p xs
```

```
[ f x y | x <- xs, y <- ys ]  
means the list  
  [(f x1 y1), ..., (f x1 yn),  
   (f x2 y1), ..., (f xm yn)]
```

which is defined by

```
flatten (map (\ x -> (map (\ y -> e) ys) xs))
```

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-10

Three-Partitions

Generate a list containing all three-partitions (nc1, nc2, nc3) of a number m, such that

- $nc1 \leq nc2 \leq nc3$
- $nc1 + nc2 + nc3 = m$

```
three_partitions m =  
  [ (nc1,nc2,nc3) | nc1 <- [0..m],  
                    nc2 <- [0..m],  
                    nc3 <- [0..m],  
                    nc1+nc2+nc3 == m,  
                    nc1 <= nc2,  
                    nc2 <= nc3 ]
```

?

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-11

Efficient Three-Partitions

```
three_partitions m =  
  [ (nc1,nc2,nc3) | nc1 <- [0..floor(m/3)],  
                    nc2 <- [nc1..floor((m-nc1)/2)],  
                    nc3 = m-nc1-nc2 ]
```

?

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-12

The Power of List Comprehensions

```
[ (i,j) | i <- [1..m], j <- [1..n] ]
```

using map

```
point i j      = (i,j)
points i       = map (point i) [1..n]
all_points     = map points [1..m]      ?
```

Is this correct?

No, we still need to flatten the list of lists.

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-13

Desugaring!

- Most high-level languages have constructs whose meaning is difficult to express precisely in a direct way
- Compilers often translate (“desugar”) high-level constructs into a simpler language
- *Two examples:*
 - *List comprehensions:* eliminate List compressions usings maps etc.
 - *Pattern Matching:* eliminate complex pattern matching using simple case-expressions

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-14

List Comprehensions: Abstract Syntax

$[e \mid Q]$ where e is an expression and Q is a list of generators and predicates

There are three cases on Q

1. First element of Q is a generator

$[e \mid x \leftarrow L, Q']$

2. First element of Q is a predicate

$[e \mid B, Q']$

3. Q is empty

$[e \mid]$

October 3, 2006

<http://www.csq.csail.mit.edu/6.827>

L08-15

List Comprehensions Semantics

Rule 1.1 $[e \mid x \leftarrow [], Q] \Rightarrow []$

Rule 1.2 $[e \mid x \leftarrow (e_x : e_{xs}), Q] \Rightarrow$
 $(\text{let } x = e_x \text{ in } [e \mid Q]) ++$
 $[e \mid x \leftarrow e_{xs}, Q]$

Rule 2.1 $[e \mid \text{False}, Q] \Rightarrow []$

Rule 2.2 $[e \mid \text{True}, Q] \Rightarrow [e \mid Q]$

Rule 3 $[e \mid] \Rightarrow e : []$

October 3, 2006

<http://www.csq.csail.mit.edu/6.827>

L08-16

Desugaring: *First Attempt*

```
TE[[ e | ]] = e : []
TE[[ e | B, Q]] =
  if B then TE[[ e | Q]] else []
TE[[ e | x <- L, Q ] ] =
  case L of
    [] -> []
    t:ts -> (let x = t in TE[[ e | Q ]])
      ++ TE[[ e | x <- ts, Q ]]
```

Will unfold infinitely!
Need to be more systematic.

Not
structural
induction

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-17

Eliminating Generators

```
[ e | x <- xs ] ⇒ map (\x-> e) xs
```

```
[ e | x <- xs, y <- ys ] ⇒
  concat (map (\x-> map (\y-> e) ys) xs)
```

where `concat` flattens a list:

```
concat [] = []
concat (xs:xss) = xs ++ (concat xss)
```

```
[ e | x <- xs, y <- ys, z <- zs ] ⇒
  concat (map (\x->
    map (\y->
      map (\z-> e) zs) ys) xs)
```

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-18

A More General Solution

- Flatten the list after each map.
- Start the process by turning the expression into a one element list

```
[ e | x <- xs ] ⇒  
  concat (map (\x-> [e]) xs)
```

```
[ e | x <- xs, y <- ys ] ⇒  
  concat (map (\x->  
    concat (map (\y-> [e]) ys)) xs )
```

```
[ e | x <- xs, y <- ys, z <- zs ] ⇒  
  concat (map (\x->  
    concat (map (\y->  
      concat (map (\z-> [e]) zs) ys) xs)
```

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-19

Eliminate the intermediate list

```
[ e | x <- xs ] ⇒ concat (map (\x-> [e]) xs)
```

Notice **map** creates a list which is immediately consumed by **concat**. This intermediate list is avoided by **concatMap**

```
concatMap f [] = []  
concatMap f (x:xs) = (f x) ++ (concatMap f xs)
```

```
[ e | x <- xs ] ⇒ concatMap (\x-> [e]) xs
```

```
[ e | x <- xs, y <- ys ] ⇒
```

```
  concatMap (\x->  
    concatMap (\y-> [e]) ys) xs
```

```
[ e | x <- xs, y <- ys, z <- zs ] ⇒
```

```
  concatMap (\x->  
    concatMap (\y->  
      concatMap (\z-> [e]) zs) ys) xs
```

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-20

List Comprehensions with Predicates

```
[ e | x <- xs, p ]  
⇒ (map (\x-> e) (filter (\x-> p) xs)  
⇒ concatMap (\x-> if p then [e] else []) xs  
  
[ e | x <- xs, p, y <- ys]  
⇒ concatMap (\x-> if p then  
  concatMap (\y-> [e]) ys) else []) xs
```

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-21

List Comprehensions:

First Functional Implementation- Wadler

```
TE[[ e | x <- L, Q]] =  
  concatMap (\x-> TE[[e | Q]]) L  
  
TE[[ e | B, Q]] =  
  if B then TE[[e | Q]] else []  
  
TE[[ e | ]] = e : []
```

Can we avoid concatenation altogether?

Idea: *Build the list from right-to-left*

```
TQ[[ e | Q ] ++ L ]
```

where L has already been translated.

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-22

Building the output from right-to-left

```
[ e | x <- xs] ⇒  
  concat (map (\x-> e) xs)
```

versus

```
[ e | x <- xs] ⇒  
  let f []      = []  
      f (x:xs') = e: (f xs')  
  in  
    (f xs)
```

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-23

Building the output from right-to-left

```
[ e | x <- xs, y <- ys] ⇒  
  concat (map (\x-> map (\y-> e) ys) xs)
```

versus

```
[ e | x <- xs, y <- ys] ⇒  
  let f []      = []  
      f (x:xs') =  
        let g []      = f xs'  
            g (y:ys') = e:(g ys')  
        in  
          (g ys)  
  in  
    (f xs)
```

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-24

List Comprehensions: *Second Functional Implementation-Wadler*

```
TE[[e | Q]]          = TQ[[e | Q]] [[]]

TQ[[e | x <- L1, Q]] [[L]] =
  let  f []          = L
        f (x:xs)     = TQ[[e | Q]] [(f xs)]
  in
    (f L1)

TQ[[e | B, Q]] [[L]] =
  if B then TQ[[e | Q]] [[L]] else L

TQ[[e | ] ] [[L]]    = e : L
```

This translation is efficient because it never flattens.
The list is built right-to-left, consumed left-to-right.

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-25

The Correctness Issue

How do we decide if a translation is *correct*?

- if it produces the same answer as some reference translation, or
- if it obeys some other high-level laws

In the case of comprehensions one may want to prove that a translation satisfies the comprehension rewrite rules.

October 3, 2006

<http://www.csg.csail.mit.edu/6.827>

L08-26
