October 26, 2006

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-1

## Outline

---

- IO Monad
  - Example: wc program
  - Some properties
- Monadic laws
- Creating our own monads:
  - Id: The simplest monad
  - State
  - Unique name generator
  - Emulating simple I/O
  - Exceptions

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-2

## Monadic I/O

---

**IO a**: computation which does some I/O,  
then produces a value of type **a**.

```
(>>)    :: IO a -> IO b -> IO b
(>>=)   :: IO a -> (a -> IO b) -> IO b
return  :: a -> IO a
```

Primitive actionspecs:

```
getChar  :: IO Char
putChar  :: Char -> IO ()
openFile, hClose, ...
```

Monadic I/O is a clever, type-safe idea which has  
become a rage in the FL community.

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-3

## Word Count Program

---

```
wcs  :: String -> Bool -> (Int,Int,Int)
      -> (Int,Int,Int)

wcs []      inWord (nc,nw,nl) = (nc,nw,nl)
wcs (c:cs) inWord (nc,nw,nl) =
    if (isNewLine c) then
        wcs cs False ((nc+1),nw,(nl+1))
    else if (isSpace c) then
        wcs cs False ((nc+1),nw,nl)
    else if (not inWord) then
        wcs cs True ((nc+1),(nw+1),nl)
    else
        wcs cs True ((nc+1),nw,nl)
```

Can we read the string from an input file as needed?

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-4

## File Handling Primitives

---

```
type Filepath = String
data IOMode = ReadMode | WriteMode | ...
data Handle = ... implemented as built-in type

openFile :: Filepath -> IOMode -> IO Handle
hClose   :: Handle -> IO ()
hIsEOF   :: Handle -> IO Bool
hGetChar :: Handle -> IO Char
```

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-5

## Monadic Word Count Program

---

```

      file name
      ↙
wc      :: String -> IO (Int,Int,Int)

wc filename =
    openFile filename ReadMode >>= \h ->
    wch h False (0,0,0) >>= \(nc,nw,nl) ->
    hClose h >>
    return (nc,nw,nl)

wch     :: Handle -> Bool -> (Int,Int,Int)
        -> IO (Int,Int,Int)

wcs     :: String -> Bool -> (Int,Int,Int)
        -> (Int,Int,Int)
```

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-6

## Monadic Word Count Program *cont.*

---

```
wch  :: Handle -> Bool -> (Int,Int,Int)
      -> IO (Int,Int,Int)
wch h inWord (nc,nw,nl) =
  hIsEOF h >= \eof ->
    if eof then return (nc,nw,nl)
    else
      hGetChar h >= \c ->
        if (isNewLine c) then
          wch h False ((nc+1),nw,(nl+1))
        else if (isSpace c) then
          wch h False ((nc+1),nw,nl)
        else if (not inWord) then
          wch h True ((nc+1),(nw+1),nl)
        else
          wch h True ((nc+1),nw,nl)
```

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-7

## Calling WC

---

```
main :: IO ()

main =   getArgs >= \[filename] ->
         wc filename >= \((nc,nw,nl) ->
           putStr "  " >>
           putStr (show nc) >>
           putStr "  " >>
           putStr (show nw) >>
           putStr "  " >>
           putStr (show nl) >>
           putStr "  " >>
           putStr filename >>
           putStr "\n"
```

Once a value enters the IO monad it cannot leave it!

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-8

## Error Handling

---

Monad can abort if an error occurs.  
Can add a function to handle errors:

```
catch :: IO a -> (IOError -> IO a) -> IO a
ioError :: IOError -> IO a
fail    :: String -> IO a

catch echo (\err ->
    fail ("I/O error: "++show err))
```

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-9

## The Modularity Problem

---

Inserting a print (say for debugging):

```
sqrt :: Float -> IO Float
sqrt x =
    let ...
        a = (putStrLn ...) :: IO String
    in a >> return result
```

Without the binding has no effect; the I/O has to be exposed to the caller:

One print statement changes the whole structure of the program!

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-10

## Monadic I/O is Sequential

```
wc filename1 >>= \(nc1,nw1,nl1) ->  
wc filename2 >>= \(nc2,nw2,nl2) ->  
return (nc1+nc2, nw1+nw2, nl1+nl2)!
```

The two `wc` calls are totally independent but the IO they perform must be sequentialized!

Monadic I/O is not conducive for parallel operations

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-11

## Syntactic sugar: `do`

```
do e                -> e  
do e ; dostmts      -> e >> do dostmts  
do p<-e ; dostmts    -> e >>= \(p-> do dostmts  
do let p=e ; dostmts -> let p=e in do dostmts
```

```
wc filename1 >>= \(nc1,nw1,nl1) ->  
wc filename2 >>= \(nc2,nw2,nl2) ->  
return (nc1+nc2, nw1+nw2, nl1+nl2)
```

*versus*

```
do (nc1,nw1,nl1) <- wc filename1  
   (nc2,nw2,nl2) <- wc filename2  
return (nc1+nc2, nw1+nw2, nl1+nl2)
```

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-12

## Are these program meaningful?

```
do (nc1,nw1,nl1) <- wc filename1
   (nc2,nw2,nl2) <- wc filename1
return (nc1+nc2, nw1+nw2, nl1+nl2)
```

```
foo = wc filename1
do (nc1,nw1,nl1) <- foo
   (nc2,nw2,nl2) <- foo
return (nc1+nc2, nw1+nw2, nl1+nl2)
```

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-13

## Monadic Laws

1.  $\text{do } x \leftarrow \text{return } a ; m \equiv (\backslash x \rightarrow \text{do } m) a$
2.  $\text{do } x \leftarrow m ; \text{return } x \equiv m$
3.  $\text{do } y \leftarrow (\text{do } x \leftarrow m ; n) ; o$   
 $\equiv \text{do } x \leftarrow m ; (\text{do } y \leftarrow n ; o)$   
 $x \notin \text{FV}(o)$

True for all monads. Only primitive operations distinguish monads from each other

```
do m ; n       $\equiv$  do _ <- m ; n
```

A derived axiom:

```
m >> (n >> o)  $\equiv$  (m >> n) >> o
```

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-14

## Properties of programs involving IO

```
putString []      = return ()
putString (c:cs) = putChar c >> putString cs
```

```
[]      ++ bs      = bs
(a:as) ++ bs      = a : (as ++ bs)
```

```
putString as >> putString bs
    ≡ putString (as++bs)
```

One can prove this just using monadic laws  
without involving I/O properties

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-15

## Monads and Let

```
1. do x <- return a ; m ≡ (\x -> do m) a
2. do x <- m ; return x ≡ m
3. do y <- (do x <- m ; n) ; o
    ≡ do x <- m; (do y <- n; o)
    x ∉ FV(o)
```

```
1. let x = a in m      ≡ (\x -> m) a
2. let x = m in x      ≡ m
3. let y = (let x = m in n) in o
    ≡ let x = m in (let y = n in o)
    x ∉ FV(o)
```

Monadic binding behaves like let

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-16

## Monads and Let

---

- Relationship between monads and let is deep
- This is used to embed languages inside Haskell
- IO is a special sublanguage with side effects

```
class Monad m where
  return :: a -> m a
  (>=)   :: m a -> (a -> m b) -> m b
  (>>)   :: m a -> m b -> m b
  fail   :: String -> m a           --*
```

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-17

## Fib in Monadic Style

---

<pre>fib n =   if (n&lt;=1) then n   else     let       n1 = n - 1       n2 = n - 2       f1 = fib n1       f2 = fib n2     in f1 + f2</pre>	<pre>fib n =   if (n&lt;=1) then return n   else     do       n1 &lt;- return (n-1)       n2 &lt;- return (n-2)       f1 &lt;- fib n1       f2 &lt;- fib n2       return (f1+f2)</pre>
----------------------------------------------------------------------------------------------------------------------------------------------	----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------

Note the awkward style: everything must be named!

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-18

## Outline

---

- IO Monad
  - Example: wc program
  - Some properties
- Monadic laws
- Creating our own monads: 
  - Id: The simplest monad
  - State
  - Unique name generator
  - Emulating simple I/O
  - Exceptions

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-19

## Id: The Simplest Monad

---

```
newtype Id a = Id a

instance Monad Id where
    return a    = Id a
    Id a >=> f = f a

runId (Id a) = a
```

- This monad has no special operations!
  - Indeed, we could just have used `let`
  - The `runId` operation runs our computation
- For IO monad `run` was done outside the language

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-20

## The State Monad

---

- Allow the use of a single piece of mutable state

```
put :: s -> State s ()
get :: State s s

runState :: s -> State s r -> (s,r)

instance Monad (State s)
```

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-21

## The State Monad: Implementation

---

```
newtype State s r = S (s -> (s,r))

instance Monad (State s) where
    return r = S (\s -> (s,r))
    S f >>= g = S (\s -> let (s', r) = f s
                           S h      = g r
                           in  h s')

get          = S (\s -> (s,s))
put s        = S (\o -> (s,()))
runState s (S c) = c s
```

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-22

## Generating Unique Identifiers

---

```
type Uniq = Int
type UniqM = State Int

runUniqM :: UniqM r -> r
runUniqM comp = snd (runState 0 comp)

uniq :: UniqM Uniq
uniq = do u <- get
        put (u+1)
        return u
```

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-23

## Poor Man's I/O

---

```
type PoorIO a = State (String, String)

putChar :: Char -> PoorIO ()
putChar c = do (in, out) <- get
               put (in, out++[c])

getChar :: PoorIO Char
getChar = do (in, out) <- get
             case in of
               a:as -> do put (as, out)
                        return a
               []    -> fail "EOF"
```

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-24

## Error Handling using Maybe

```
instance Monad Maybe where
  return a = Just a
  Nothing >=> f = Nothing
  Just a >=> f = f a
  fail _ = Nothing

Just a `mplus` b = Just a
Nothing `mplus` b = b

do m' <- matrixInverse m
  y <- matrixVectMult m x
  return y
```

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-25

## Combining Monads

- To simulate I/O, combine State and Maybe.
- There are two ways to do this combination:

```
newtype SM s a = SM (s -> (s, Maybe a))
newtype MS s a = MS (s -> Maybe (s, a))
```

	SM	MS
	([], "")	([], "")
do putChar 'H'	([], "H")	([], "H")
a <- getChar	([], "H")	Nothing
putChar 'I'		<i>skipped</i>
`mplus` putChar '!'	([], "H!")	([], "I!")

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-26

## Special Monads

---

- Operations inexpressible in pure Haskell
- IO Monad
  - Primitives must actually call the OS
  - Also used to embed C code
- State Transformer Monad
  - Embeds *arbitrary* mutable state
  - Alternative to M-structures + barriers

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-27

## Extras

---

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-28

## Monadic Laws

1. `return a >=> \x -> m ≡ (\x -> m) a`
2. `m >=> \x -> return x ≡ m`
3. `(m >=> \x -> n) >=> \y -> o  
≡ m >=> \x -> (n >=> \y -> o)  
x ∉ FV(o)`

True in every monad by definition. Primitive monadic operators distinguish one monad from another

A derived axiom:

$$m \gg (n \gg o) \equiv (m \gg n) \gg o$$

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-29

## Base case

```
putString [] = return ()
```

```
[] ++ bs = bs
```

```
putString [] >> putString bs  
≡ return () >> putString bs  
≡ putString bs  
≡ putString ([] ++ bs)
```

October 26, 2006

<http://www.csg.csail.mit.edu/6.827>

L13-30

## Inductive case

---

```
putString (a:as) = putChar a >> putString as
```

```
(a:as) ++ bs      = a : (as ++ bs)
```

```
putString (a:as) >> putString bs
≡ (putChar a >> putString as) >> putString bs
≡ putChar a >> (putString as>>putString bs)
≡ putChar a >> (putString (as ++ bs))
≡ putString (a : (as ++ bs))
≡ putString ((a:as) ++ bs)
```
